## APPENDICES

I Metallurgical Section of December 2012 Technical Report
II List of Drill Holes Used for Mineral Resource Calculations
III Semivariograms for Silver, Lead, Zinc, Copper, Tin, Indium and Cadmium within the Mineralized Solid and in Waste Used for Mineral Resource Calculations
IV Specific Gravity Determinations Used for Mineral Resource Calculations

### 1.0 SUMMARY

Silver Range Resources Ltd. (Silver Range) retained Giroux Consultants Ltd. and Melis Engineering Ltd. to complete a National Instrument 43-101 (NI 43-101) Technical Report for the purpose of supplying updated information to its shareholders. This report was written in compliance with the disclosure and reporting requirements set forth in the Canadian Securities Administrators' National Instrument 43-101 (NI 43-101), Companion Policy 43-101CP and Form 43-101F1.

This Technical Report provides the first resource estimate for Keg Main Zone, which is the most advanced exploration target within the Keg Property, south-central Yukon. The Keg Property consists of 4,744 mineral claims that are $100 \%$ owned by Silver Range. This report focusses only on the 89 mineral claims that cover Keg Main Zone and adjacent Keg East Zone. These claims are referred to as the "Property" throughout this report. The Property encompasses a 2,002 ha area located approximately 40 km north of the town of Faro.

### 1.1 Geology and Mineralization

The Property lies within an area underlain by various Paleozoic-age strata, which have been juxtaposed by a complex series of Jurassic to Cretaceous high angle and thrust faults. Regionally, the stratified rocks have been intruded and altered by Mid-Cretaceous igneous bodies that range up to batholith in size and from granodiorite to syenite in composition. No intrusive rocks are known within the Property.

Keg Main Zone is a bulk-tonnage silver-lead-zinc-copper $\pm$ tin $\pm$ indium prospect situated about 25 km north of formerly producing zinc-lead-silver mines of the Anvil District. Mineralization within Keg Main Zone has been traced by drilling for a length of 1100 m , across approximate true widths of 50 to 250 m through a vertical depth of 350 m starting from surface. The zone remains open to extension. Mineralization is hydrothermal in origin and occurs as fracturefilling and in skarn/replacement horizons, with an observed mineral assemblage that consists of pyrrhotite with lesser sphalerite, chalcopyrite, pyrite, arsenopyrite, galena and stannite.

### 1.2 History and Exploration

The first significant discovery in the area was made in 1953, when the Vangorda sedimentary exhalative (sedex) deposit was identified. No further discoveries were made until 1965, when the Faro Deposit was found. This major deposit stimulated a large staking rush and extensive exploration throughout the area. Over the next 20 years, exploration resulted in identification of additional sedex deposits, which define a narrow, northwesterly trending belt (Anvil Belt). Three deposits in this belt have been mined (Vangorda, Faro and Grum), while two others (Grizzly and Swim) are partially developed. In the 1960s and 1970s, several exploration programs were conducted northeast of the Anvil Belt in the vicinity of the Property, but they were deemed to be unsuccessful because sedex style mineralization was not found.

Between 1965 and 1978, several operators worked within the boundaries of the current Property. Although strong geochemical and geophysical anomalies were detected, follow up drilling
intersected only fracture-filling and skarn/carbonate replacement style mineralization, which was dismissed because the focus of exploration was on massive sulphide deposits. After 1978, work in the area tapered off.

In 2010, Strategic Metals Ltd. (Strategic Metals) staked claims over Keg Main and Keg East Zones and, in 2012, it sold the claims to Silver Range. Strategic Metals and Silver Range contracted Archer Cathro to conduct the 2010 to 2012 exploration programs on the Property. Exploration to date has included regional and detailed scale, soil geochemical and geophysical surveys; prospecting; geological mapping; environmental, heritage and access studies; and diamond drilling ( $23,014.51 \mathrm{~m}$ in 69 holes).

### 1.3 Mineral Processing and Metallurgical Testing

Metallurgical testwork on Keg Main Zone was completed on six variability composites representing distinct zones of the known mineralization and one overall composite prepared as a blend of the six variability composites. The work encompassed preparation and analyses of test composites, comminution testing, open cycle and lock cycle flotation tests, gravity recovery tests, concentrate analyses and tailings physical and chemical characterization. Metallurgical testwork was carried out at SGS Canada Inc. - Lakefield Research under the direction of Lawrence A. Melis, P.Eng. of Melis Engineering Ltd. Mr. Melis is a qualified person and independent of the issuer, based on the guidelines provided by NI 43-101.

Key head analyses of the composites used in the testwork are summarized in Table 1-1 below.

Table 1-1: Test Composites - Assay Head Grades for Key Elements

| Composite | Ag (g/t) | Cu (\%) | Pb (\%) | Zn (\%) | In (g/t) | Sn (g/t) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Overall | 41.6 | 0.27 | 0.31 | 1.36 | 11.4 | 400 |
| A | 89.1 | 0.18 | 0.62 | 0.69 | 1.7 | 770 |
| B | 56.2 | 0.60 | 0.30 | 2.30 | 15.6 | 760 |
| C | 44.1 | 0.31 | 0.34 | 1.67 | 13.1 | 230 |
| D | 32.3 | 0.10 | 0.27 | 0.89 | 8.8 | 100 |
| E | 21.1 | 0.14 | 0.15 | 1.28 | 19.5 | 210 |
| F | 32.7 | 0.19 | 0.28 | 1.14 | 9.1 | 360 |

The results of the lock cycle tests on all test composites show that Keg Main Zone mineralization responds very well to typical copper/lead/zinc flotation circuits with excellent recoveries of payable metals and acceptable copper, lead and zinc concentrate grades in copper, lead and zinc concentrates. Results of the lock cycle tests are summarized in Table 1-2.

Table 1-2: Summary of Lock Cycle Test Results

### 1.4 Mineral Resource Estimate

The inferred mineral resource for the Keg Main Zone comprises 39,760,000 t grading 30.25 $\mathrm{g} / \mathrm{t}$ silver, $0.26 \%$ lead, $0.77 \%$ zinc, $0.15 \%$ copper, 265.7 ppm tin, 5.77 ppm indium and 138.06 ppm cadmium. This resource is stated above a $16.0 \mathrm{~g} / \mathrm{t}$ silver cut-off grade. A summary of inferred mineral resources at various cut-off grades is provided in Table 1-3.

Table 1-3: Inferred Mineral Resource

| Cut-off (Ag g/t) | $\begin{gathered} \text { Tonnes > } \\ \text { Cut-off } \\ \text { (tonnes) } \\ \hline \end{gathered}$ | Grade > Cut-off |  |  |  |  |  |  |

The Keg Main Zone mineral resource estimation was completed by Gary Giroux, P.Eng., MASc. of Giroux Consulting Ltd. Mr. Giroux is a qualified person and independent of the issuer, based on the guidelines provided by NI 43-101.

Data generated during the various drill programs conducted at Keg Main Zone were independently reviewed by Giroux Consultants Ltd. The resource estimate for Keg Main Zone was initiated using a wire-frame 3D solid model in "GEMS." Three-dimensional solids were manually digitized from the available drill data and were used to constrain the interpolation of mineralization. The model was constructed based upon lithological boundaries and structural controls. A total of three different lithological units were used in the modelling process.

Drill holes were "passed through" this geologic solid with the entry and exit points recorded. Using this information the assays were "back tagged" with different codes if inside or
outside the solid. Of the 69 supplied drill holes, 53 holes totalling $18,376.81 \mathrm{~m}$ intersected the mineralized solid.

A block model with blocks $20 \times 20 \times 5 \mathrm{~m}$ in dimension was superimposed over the mineralized solid. For each block, the percentage below surface topography and within each mineralized solid was recorded.

The bulk density for rock within Keg Main Zone was established from 907 specific gravity determinations using the weight in air - weight in water procedure. There is a wide range of specific gravities in most of the rock types and the specific gravity of any given sample is more a function of sulphide content than host rock type. As a result, a specific gravity value was interpolated into each block in the model using the inverse distance squared procedure.

Uniform, five metre long, down-hole composites were produced to honour the mineralized solid. Grades for the elements of interest were interpolated into blocks within the mineralized solid using Ordinary Kriging. The kriging exercise was completed in a series of four passes. Appropriate block model validation techniques for resource estimation at this stage of project development were applied.

A cut-off silver grade of $16.0 \mathrm{~g} / \mathrm{t}$ will be used for the reported resource estimate until a Preliminary Economic Assessment (PEA) is conducted for the project and a cut-off grade can be chosen to match economic criteria.

### 1.5 Interpretation and Conclusions

Keg Main Zone is a relatively shallow, bulk-tonnage silver-lead-zinc-copper $\pm$ tin $\pm$ indium deposit situated north of the formerly producing mines of the Anvil District. The deposit is distinguished from Anvil District deposits and other large base metal showings and deposits elsewhere in Yukon by its uncommonly high silver contents relative to contained base metals and by its enrichments of tin, indium and other relatively rare metals.

Keg Main Zone is favourably situated in an area where several regional structural elements occur close together. This cluster of large-scale structures likely played an important role in ground preparation for the deposit. The deposit is hosted in strongly altered and folded siliceous siltstone and chert, which may have been deformed by a buried thrust fault that failed to break through these units. During folding of siliceous siltstone and chert, small scale fracturing produced permeability in the otherwise relatively impermeable rocks.

In addition to the ground preparation described above other elements likely play roles in the development of mineralization within Keg Main Zone. The folded and fractured siliceous siltstone and chert are interbedded with silty limestone and calcareous siltstone, which are the most reactive rocks in the area. Fluids channeling through the fractured siliceous siltstone and chert likely flowed upwards or laterally into the reactive stratigraphy. A small intrusive plug located approximately two kilometres south of the deposit may have provided a local heat source that powered at the mineralizing hydrothermal cell. Late normal and dip-slip faults crosscut the
folded siliceous siltstone and chert and may have acted as deep-seated fluid conduits that localized hydrothermal flow.

Exploration conducted to date at Keg Main Zone has defined a sizeable mineral resource, and metallurgical testwork has produced encouraging results. Keg Main Zone is very well situated in regards to infrastructure. Further work is warranted.

### 1.6 Recommendations

Silver Range should conduct: a scoping level economic evaluation; additional diamond drilling targeted at better defining and expanding the Keg Main Zone mineral resource; further metallurgical test work; and additional geotechnical, climatic, heritage and environmental studies.

Infill diamond drilling should be completed to upgrade the mineral resource from inferred to indicated or measured. Drilling should also be conducted to determine whether the deposit can be extended further to depth and/or along strike. Larger diameter drill core should be used in some holes to aid in additional metallurgical testwork, and oriented drill core should be obtained to provide data to support preliminary pit slope design for conceptual pit walls.

A Preliminary Economic Assessment has been initiated and evaluation of road access routes is being done. Current environmental and heritage base line studies should be continued, and piezometers should be installed for ground water monitoring.

The ongoing and proposed work programs that encompass the work above are budgeted at a total cost of $\$ 3,946,800$.

### 2.0 INTRODUCTION

This Technical Report has been prepared at the request of the Board of Directors of Silver Range Resources Ltd. in order to summarize results of metallurgical testwork and provide a formal mineral resource estimate for Keg Main Zone. The mineral resource estimate was prepared using drill data generated between June 2010 and September 2012. This report was written in compliance with disclosure and reporting requirements set forth in the Canadian Securities Administrations' current "Standards of Disclosure for Mineral Projects" under the provisions of National Instrument 43-101 (NI 43-101), Companion Policy 43-101 CP and Form 43-101F1.

The core of the Property was staked in winter 2009-2010 by Strategic Metals Ltd., which completed the 2010 and initiated the 2011 exploration programs before selling the Property to Silver Range on August 9, 2011 through a plan of arrangement.

Silver Range is listed on the TSX Venture Exchange (TSX-V) and holds a $100 \%$ interest in the Property, without underlying royalty interests.

Gary Giroux, P.Eng., visited the Property on August 31 and September 1, 2011 and was retained to prepare the mineral resource estimate and accompanying technical report. Lawrence A. Melis, P.Eng. has not visited the Property.

### 3.0 RELIANCE ON OTHER EXPERTS

This report includes a study of information obtained from: public documents, assessment reports and literature sources cited in Section 20.0; geological work performed by Strategic Metals and Silver Range; metallurgical testwork; and, a mineral resource estimate. The Author used his experience to determine if the information provided was suitable for inclusion in this technical report and adjusted information that required amending.

Mineral Claim Information was provided by the office of the Yukon Mining Recorder. Although Global Positioning Satellite (GPS) surveys were carried out to verify the approximate claim locations as shown on government claim maps and as referred to on maps that accompany this report, these surveys have no legal standing and do not guarantee land tenure.

### 4.0 PROPERTY DESCRIPTION AND LOCATION

The Property is located in the Whitehorse Mining District within south-central Yukon and is centred at latitude $62^{\circ} 35^{\prime}$ north and longitude $133^{\circ} 19^{\prime}$ west on NTS map sheet $105 \mathrm{~K} / 11$ (Figure 1).

The Property comprises 89 mineral claims that cover an area of 2,002 hectares. The claims are registered in the name of Archer, Cathro \& Associates (1981) Limited (Archer Cathro), which holds them in trust for Silver Range. Silver Range owns the Property and there are no underlying royalty interests. Specifics concerning claim registration are tabulated below, while the locations of individual claims are shown on Figure 2.

| Tenure Name |  | Tenure Number |  |
| :--- | :--- | :--- | :--- |
| Keg 1-15 |  | YD11773-YD1178 Date* |  |
| Keg 16-53 |  | YD33666-YD33703 | March 13, 2019 |
| Keg 94-115 |  | YD62994-YD63015 |  |
| March 13, 2020 2020 |  |  |  |
| Keg 122-123 |  | YD63022-YD63023 | March 13, 2020 |
| Keg 130-131 |  | YD63030-YD63031 | March 13, 2020 |
| Keg 138-145 | YD63038-YD63045 | March 13, 2020 |  |
| Keg 373 | YD27423 | March 13, 2020 |  |
| Keg 375 | YD27425 | March 13, 2020 |  |

*Expiry dates include 2012 work expenditures that have been filed for assessment credit but approval is pending until the Mining Recorder officially accepts the assessment report describing work to which those expenditures apply.

The claims were located using handheld GPS units and are plotted on Figure 2 in the UTM NAD83 coordinate system.

In Yukon, mineral claims can be maintained in good standing by performing approved exploration work to a dollar value of one hundred dollars (\$100) per claim per year. Exploration and development expenditures in the current anniversary year may be applied to a maximum of five future anniversary years, and those anniversary years may be added to any previous surplus of anniversary years.

Exploration work in Yukon is subject to the Mining Land Use Regulations of the Yukon Quartz Mining Act and to the Yukon Environmental and Socio-Economic Assessment Act. A Land Use approval must be obtained and Yukon Environmental and Socio-Economic Assessment Board recommendations issued before advanced exploration may be conducted. The Property is currently subject to a Class III Mining Land Use Approval (LQ00318), which authorizes Silver Range to upgrade or establish camps, build and maintain certain trails and access roads and carry out geological mapping, prospecting, soil sampling, line cutting and surface diamond drilling with settling ponds and sumps. This approval is valid until June 14, 2016.

The Property is subject to regular inspections by Land Use officials. The only outstanding environmental liability known to the Author is Silver Range's obligation to reclaim the camp,

roads and drill pads prior to the expiration of its current Land Use approval. The Author does not know of any impediments to Silver Range's surface rights of the Property.

### 5.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

The Property lies 40 km north of the town of Faro, which is the nearest supply centre. Faro can be reached in all seasons by two wheel drive vehicles using the Yukon highway system from Whitehorse, the territorial capital and main transportation hub. Faro is located 356 km by road from Whitehorse.

Faro formerly serviced the mines and mill of the Anvil District. A heavy duty haulage road and a high voltage power line extend from the town site to the Faro mine and mill site, which are located 25 km south of the Property through low hilly terrain. Electricity for the power line comes from a hydroelectric dam and diesel generators, located in Whitehorse. At present, there is no excess capacity on the Yukon electrical grid, but the Government of Yukon is currently studying the viability of liquefied natural gas fired, electrical generation plants.

Portable electrical generators provide sufficient power for exploration stage programs on the Property. Creeks on the Property provide sufficient water for camp and diamond drilling requirements. The Property has sufficient sites for mining, administrative and camp buildings, potential tailings storage, potential waste disposal and potential processing plants, with no conflicting surface rights.

The majority of supplies and services required for mineral exploration are available in Whitehorse. Many services are also available in Faro including a hotel, a restaurant, limited fuel sales, a first aid station, an all-weather airport, various types of aircraft and an RCMP detachment. There are a number of vacant houses, apartment complexes and commercial buildings in Faro, and many undeveloped lots.

In 2012, access to the property and daily logistical support were provided by an Eurocopter AStar B3 helicopter, a Bell 206B helicopter and a Hughes 500D helicopter, all based on the Property or at the Faro airport. All three helicopters were operated by Trans North Helicopters of Whitehorse, Yukon. Rented lots at the Faro airport served as a logistical staging area.

The Property is situated in the Anvil Range of the Pelly Mountains and is drained by creeks that flow into the Tay River, which ultimately connects to the Pacific Ocean via the Pelly and Yukon Rivers. One creek and one small lake on the Property have been assigned informal names (Ivan Creek and Marijke Lake) for the sake of this report (Figure 2).

The Property covers an east-west trending, relatively flat-topped ridge that is truncated to the east by Ivan Creek. Elevations on the Property range between 820 m and 1400 m above sea level. The main areas of interest lie along the northern edge of the ridge, which crests at or just below treeline. Slopes near treeline are vegetated primarily with staghorn moss, thick brush and stunted spruce and poplar trees. The density and size of vegetation gradually increases on lower slopes. Mature spruce forests are only found on south facing slopes and along Ivan Creek.

Understory comprises dwarf birch and mountain alder, with a thick layer of sphagnum moss. Due to a combination of shade, locally poor drainage and a thick insulating blanket of sphagnum moss, permafrost is prevalent on north facing slopes. Outcrop is rare within the Property.

Much of the overburden in the region is associated with the most recent Cordilleran ice sheet, the McConnell glaciation, which is believed to have covered south and central Yukon between 26,500 and 10,000 years ago (Yukon Geological Survey, 2010a). Tay River map area was covered by the Selwyn Lobe of the Cordilleran ice sheet. A complex system of ice-caps and cirque glaciers was active at high elevations in the Pelly Mountains and contributed to the ice bodies surrounding them.

The climate at the Property is typical of northern continental regions with long, cold winters, truncated fall and spring seasons and short, mild summers. Although summers are relatively warm, snowfall can occur in any month at higher elevations. The Property is mostly snow free from late May to late September. According to Environment Canada, summer temperatures in the town of Faro average 18 to $21^{\circ} \mathrm{C}$ during the day and 6 to $9^{\circ} \mathrm{C}$ at night (Environment Canada, 2010). Winter temperatures average -17 to $-10^{\circ} \mathrm{C}$ during the daytime. Total annual precipitation over the 1971 to 2000 period averaged 316 mm , with little over two-thirds falling as rain and about 110 cm as snow.

### 6.0 HISTORY

Historical exploration was largely compiled from assessment reports submitted to the Yukon Mining Recorder. These reports were not prepared in accordance with the standards prescribed in NI 43-101. Nonetheless, they were accepted by the Yukon Mining Recorder and were consistent with professional standards at the time they were written.

Apart from prospecting for placer gold early in the $20^{\text {th }}$ century and reconnaissance-scale mapping done by the Geological Survey of Canada in the 1930s (Johnston, 1936), there was no reported exploration activity in the Faro area until the Canol Road was built during World War II, thus providing better access to the district (Wober, 1967). The first significant discovery in the area was made in 1953, when Prospector Airways identified sedimentary exhalative (sedex) style, zinc-lead-silver mineralization at the Vangorda Deposit (Figure 1). No further discoveries were made until 1965, when Dynasty Explorations and Cypress Mining Corp. Ltd. found similar mineralization at the nearby Faro Deposit. This larger deposit stimulated a staking rush and extensive exploration throughout the area by various operators (Cathro, 1967).

Over the next 20 years, exploration resulted in identification of additional sedex deposits, which define a narrow, northwesterly trending belt (Anvil Belt). Three deposits in this belt have been mined (Vangorda, Faro and Grum), while two others (Grizzly and Swim) are partially developed. Several exploration programs were conducted northeast of the Anvil Belt in the vicinity of the Property, but they were deemed to be unsuccessful because sedex style mineralization was not found.

Between 1965 and 1978, numerous operators worked within the boundaries of the current Property. Although strong geochemical and geophysical anomalies were detected, follow up
drilling intersected only fracture-filling and skarn/carbonate replacement style mineralization, which was dismissed because the focus of exploration was on massive sulphide, sedex deposits. After 1978, work in the area tapered off. Table 6-1 lists the year of work, owner/operator, claim group name, work performed and highlight results for each program, while Figure 3 illustrates the relative locations of many of the old claim blocks.

Table 6-1 Exploration History (after Deklerk and Traynor, 2005)

| Year of Work (Report \#) | Owner/ Operator | Claim Group | Work Performed | Results |
| :---: | :---: | :---: | :---: | :---: |
| $1965$ <br> (Minfile) | Anvil Mining Corporation Ltd. | Ivan | Staked claims following an airborne magnetic (mag) and electromagnetic (EM) survey | n/a |
| 1966 $(091262)$ (Adamson, 1966) | Anvil Mining | Ivan | Diamond drilling (464.5 $m$ in 4 holes) | Intersected disseminated $\mathrm{Pb}-\mathrm{Zn}$ mineralization, but no sulphides of economic significance observed, no assaying done. |

| $\begin{gathered} 2010 \\ \text { (Eaton, 2011) } \end{gathered}$ | Strategic Metals Ltd. | Keg | Staked claims <br> Prospecting Geochemical survey IP survey VTEM \& mag survey Diamond drilling ( 958.27 m in 4 holes) | Best drill intercept returned $50.09 \mathrm{~g} / \mathrm{t} \mathrm{Ag}, 1.20 \% \mathrm{Zn}, 0.65 \%$ $\mathrm{Pb}, 0.14 \% \mathrm{Cu}, 217 \mathrm{ppm} \mathrm{Sn}$ over 125.70 m . Identified several additional soil anomalies and mineralized zones. |
| $\begin{gathered} 2011 \\ \text { (Eaton, 2012) } \end{gathered}$ | Strategic Metals -Silver Range Resources Ltd. | Keg | Property sold by Strategic Metals to Silver Range | n/a |
| 2011 | Strategic | Keg | Claim staking | Best drill intercepts returned |

The exploration programs and results from trenching and diamond drilling are described in more detail in the following paragraphs. Results from historical soil geochemical sampling are compiled and discussed along with more recent work by Strategic Metals and Silver Range in Section 10.0.

Much of the Property was initially staked in 1965 as the Ivan claims by Anvil Mining Corporation Ltd., following regional airborne magnetic and electromagnetic (EM) surveys.

In 1966, Anvil Mining completed 464.5 m of diamond drilling in four holes at the centre of the Ivan claim block to follow up 1965 geophysical targets (these holes were drilled in vicinity of Keg East Zone). No thick sections of massive sulphides were intersected and, therefore, none of the core was analyzed. The presence of minor disseminated, blebby and banded pyrite and pyrrhotite with rare galena, sphalerite and chalcopyrite was noted in many intervals in all holes. Several narrower bands (up to 12 cm thick) of semi-massive to massive sulphides were intersected. The Ivan claims were allowed to lapse.

Also in 1966, Yukon Copper Ltd. staked the Caribou Lake property (Tara, Dane and Hal claims) around the Ivan claim block. Yukon Copper conducted soil sampling, geological mapping and airborne magnetic and EM surveys. Later that year, Yukon Copper reorganized as Northern Empire Mines Ltd.

In 1967, Northern Empire carried out soil and rock geochemical sampling, geological mapping and line cutting. Near the end of the 1967 exploration season, Northern Empire began bulldozer trenching on the Hal claims. The trenching program was terminated early due to frozen ground. The following year, the bulldozer trenching was completed. A total of about 15,300 cubic metres of bedrock and frozen overburden was removed from nine trenches. Widespread, weakly disseminated pyrrhotite, chalcopyrite and sphalerite and rare galena were reportedly encountered, but this material was not systematically sampled. Heavily disseminated to massive sulphide mineralization was found in two places. It consists of a pyrrhotite-pyrite-sphalerite assemblage, with lesser amounts of chalcopyrite, galena and scheelite. Four grab samples collected from one location in 1967 yielded between 6.2 and $11 \mathrm{~g} / \mathrm{t}$ silver, 2.8 and $4.5 \%$ zinc, 0.04 and $0.18 \%$ copper and 0.34 and $0.68 \mathrm{~g} / \mathrm{t}$ gold. When better exposed by further bulldozing in 1968 , this showing proved to consist of a sulphide lens less than 15 m long and 3 m wide that averaged $3.4 \mathrm{~g} / \mathrm{t}$ silver, $1.25 \%$ zinc and $0.05 \%$ copper. At the second location, the upper 2.4 m of a massive, pyrrhotiterich band was exposed. A chip sample of this mineralization assayed $2.84 \%$ zinc, $0.01 \%$ lead, $0.37 \%$ copper with trace gold and silver across the exposed 2.4 m width.

In 1969, Inter-Tech Development and Resources Ltd. restaked the old Ivan claims as the Ter claims. No work was reported for these claims and they subsequently expired.

In 1971, Northern Homestake Mines Ltd. acquired the Caribou Lake property from Northern Empire.

In 1972, Northern Homestake completed additional bulldozer trenching on the Hal claims, but there is no record of the amount of work performed or results obtained from it. That same year, Ridgemont Mining Corporation, a subsidiary of Cyprus Anvil Mining Corporation, restaked the old Ivan/Ter claims as the Dana claims. It also staked the Irma claims to the northwest.

In 1973, Ridgemont Mining optioned the Hal claims from Northern Homestake. Ridgemont Mining performed soil sampling on its Dana claims.

In 1974, Ridgemont Mining added the Halo claims to fill a gap between the Hal and Dana claim blocks. It also conducted geochemical surveys, geological mapping and magnetic, EM and induced polarization (IP) surveys on both the Hal and Halo claims. No description of this work nor results obtained from it is available. Later that year, Ridgemont Mining transferred the Dana, Irma, Hal and Halo claims to Cyprus Anvil, which completed 494 m of diamond drilling in three holes on the Hal and Halo claim blocks (within Keg Main Zone). These holes intersected variably fractured, mineralized and altered siliceous rocks with narrower, interbedded skarn horizons. Sulphide minerals comprise pyrrhotite with lesser pyrite, sphalerite, chalcopyrite, galena and arsenopyrite. These minerals occur as disseminations, fine to coarse blebs, fracture coatings, matrix in crackle breccias and rarely as bands in the skarn horizons. The core was only sampled intermittently. The best interval of contiguous samples yielded weighted averages of $34.3 \mathrm{~g} / \mathrm{t}$ silver, $1.25 \% \mathrm{zinc}, 0.47 \%$ lead and $0.14 \%$ copper over 49.1 m .

In 1975, Cyprus Anvil drilled 627 m in three holes to test along strike and down-dip of the mineralization discovered in its 1974 holes (within Keg Main Zone). Less extensive, but locally higher grade mineralization was intersected in the 1975 holes, which were also sampled intermittently. The most significant intersections graded $1.24 \%$ zinc over 11.6 m and $0.82 \%$ zinc over 24.1 m . Copper and lead values were low in both holes and no silver results were reported. That year, Cyprus Anvil also conducted magnetic and gravity surveys on the Irma claims.

In 1977, Cyprus Anvil followed up the 1975 Irma geophysical work with an IP survey. In 1978, one hole totalling 159 m was drilled to test the geophysical targets. No assays were reported for this hole.

All claims in the area subsequently expired. In 1990, YGC Resources Ltd. staked the Keg claims to cover the most significant historical geochemical and geophysical anomalies, bulldozer trenches and diamond drill holes (Keg Main Zone area). It completed minor prospecting and geochemical sampling. These claims were also allowed to expire without receiving significant work.

Prospector R. Berdahl staked the BP4 claim (west of Keg Main Zone) in 2007. No work was filed on this claim by Berdahl.
In 2010, Strategic Metals staked claims, optioned the BP4 claim and subsequently completed prospecting, road building, line cutting, diamond drilling ( 958.27 m in four holes in the vicinity of the 1974 and 1975 holes) and geochemical, IP, VTEM and magnetic surveys. Results from this work are discussed in Sections 9.0 and 10.0.

In 2011, Strategic Metals initiated a comprehensive exploration program on the Keg claims, which was completed by Silver Range after sale of the claims was completed on August 11, 2011 through a plan of arrangement. The combined 2011 program included additional claim staking, prospecting, geological mapping, line cutting, road building, diamond drilling ( $16,808.37 \mathrm{~m}$ in 51 holes), petrographic studies and geochemical, IP, water quality and wildlife surveys. Results from this work are discussed in Section 9.0 and 10.0.

The BP4 claim, which is located about 500 m west of Keg Main Zone, was not sold to Silver Range along with Strategic Metals' wholly owned Keg claims, because earn-in on the option had not been completed. In fall 2012, Strategic Metals acquired a $100 \%$ interest in the BP4 claims, subject to a net smelter return royalty interest.

There have been no historical mineral resource estimates for the Property and it has never been put into production.

### 7.0 GEOLOGICAL SETTING

### 7.1 Regional Geology

The Property lies about 25 km north of the Anvil District, which has been the focus of numerous government and industry sponsored studies since the discovery of the Vangorda Deposit in 1953. Regional bedrock geology for Tay River map area (105K) was published at 1:253440 scale by Roddick and Green 1961) and at 1:250000 scale by Gordey and Irwin (1987). More detailed studies by Tempelman-Kluit (1972) at 1:125000 scale and Gordey (1990a and b) at 1:50000 scale were completed following the discovery of more massive sulphide, sedex deposits in the area (Pigage, 2004). These discoveries also led to extensive detailed mapping by mining and exploration companies. The Yukon Geological Survey (YGS) integrated the results of past government studies and company exploration, along with its own more recent mapping in the Anvil District, and published a compilation in 2004 (Pigage, 2004). The following geological descriptions are largely summarized from the published data.

The Property is located within Selwyn Basin (Figure 4), a tectonic element comprising deep water clastic rocks, chert and minor carbonate that accumulated along the North American continental margin during Paleozoic time. The basin is bound to the northeast by a carbonate platform (Mackenzie Platform), which formed the near-shore facies of ancient North America (Abbott et al, 1986).

In the Property area, Selwyn Basin lies immediately northeast of units belonging to Slide Mountain and Yukon-Tanana Terranes, the most easterly of the allochthonous terranes (Coney et

SILVER RANGE RESOURCES LTD.
FIGURE 4
ARCHER, CATHRO \& ASSOCIATES (1981) LIMITED
TECTONIC SETTING
KEG PROPERTY
al, 1980). Deformation and metamorphism associated with accretion of the allochthonous terranes was initiated in Jurassic and culminated in Cretaceous (Tempelman-Kluit, 1979). More recently, strike-slip faulting along the Tintina Fault resulted in about 450 km of dextral offset during Early Tertiary time (Roddick, 1967; Murphy and Mortensen, 2003). The Property lies about 40 km northeast of the Tintina Fault.

The rocks in the vicinity of the Property comprise various Paleozoic-age strata that have been juxtaposed by a complex series of Jurassic to Cretaceous high angle and thrust faults (Figure 5). Structure in the area is dominated by moderately southwest-dipping or flat-lying strata that are imbricated by several large northwest-trending, northeast directed thrust faults (Yukon Geological Survey, 2010b).

The Paleozoic strata are sandwiched between two major Mid-Cretaceous igneous bodies - the Anvil Batholith to the southwest and the Teddy Caldera to the northeast. The Anvil Batholith belongs to Selwyn Plutonic Suite, which consists of intermediate (biotite quartz monzonite, granodiorite and minor diorite) to more felsic (biotite $\pm$ hornblende $\pm$ muscovite granite, quartz monzonite, granodiorite) compositions. The Teddy Caldera is part of South Fork Volcanics, which comprise biotite-quartz-hornblende-feldspar crystal tuff. Both igneous bodies are elongated parallel to the regional northwest to southeast structural trend.

The youngest igneous event in the area comprises bimodal volcanics and feeder plugs of Early Tertiary age. These bodies are often too small to map at regional-scale. They are assigned to the Ross Volcanics. All units in the area are described in detail in Table 7-1.

Table 7-1: Lithological Units (after Gordey, 1990a,b)

| Unit Name | Age | Map Name | Description |
| :---: | :---: | :---: | :--- |
| Ross <br> Volcanics | Lower <br> Tertiary | ITR2 | Rhyolite flows, tuffs, ash-flow tuffs and breccias, <br> locally laminated; small stocks and necks of white <br> weathering, flow-banded, quartz-sanidine <br> porphyry to granite porphyry, locally obsidian <br> bearing; local shale, sandstone and conglomerate. |
| South Fork <br> Volcanics | Mid- <br> Cretaceous | KSF | Dark brown weathering, locally columnar jointed, <br> massive, densely welded, biotite-quartz- <br> hornblende-feldspar crystal tuff. |
| Selwyn Suite | Mid- <br> Cretaceous | $\mathrm{mK}(\mathrm{g}, \mathrm{q}) \mathrm{S}$ | Plutonic suite of intermediate (g) to more felsic <br> composition (q): <br> g. resistant, blocky, fine to coarse grained <br> equigranular to porphyritic (K-feldspar) biotite <br> quartz monzonite and granodiorite and minor <br> quartz diorite; minor leuco-quartz monzonite and <br> syenite. <br> q. equigranular to porphyritic (K-feldspar) biotite <br> +/- hornblende +/- muscovite granite, quartz <br> monzonite and granodiorite; porphyritic biotite <br> hornblende granite with large smoky grey quartz <br> phenocrysts and locally K-feldspar phenocrysts. |

A large area between the southeast corner of the Property and the Teddy Caldera is blanketed by unconsolidated Quaternary glacial, glaciofluvial and glaciolacustrine deposits.

Regional metamorphism within Selwyn Basin is typically lower greenschist facies. Contact metamorphism is developed around Cretaceous plutons (Yukon Geological Survey, 2010b). Contact aureoles are up to several kilometres in diameter and produce calc-silicate, pelitic and siliceous hornfels.

### 7.2 Property Geology

Detailed mapping carried out in the summers of 2011 and 2012 by Silver Range centered on the Keg Main Zone. This mapping was hampered by the paucity of bedrock exposures in the area.

The Property is underlain by Upper Cambrian through Permian aged sedimentary rocks that are classified regionally as Rabbitkettle Formation, Earn Group, Tay Formation and Mount Christie Formation. Figure 6 shows detailed plan view geology of the Property, while Figure 7 (stratigraphic column) and Figure 8 (cross-section) illustrate the relationships between the units.

The oldest exposed rocks in this area have been grouped as Upper Cambrian to Lower Ordovician Rabbitkettle Formation (CORT). Where exposed they comprise dark grey to greybrown and sometimes white, laminated to thinly bedded, quartzose siltstone and fine-grained sandstone with minor shale horizons. Buff weathering, fine-grained sandstone is locally interbedded with siltstone. The most northwesterly exposure of this unit comprises grey, quartzrich siltstone with laminations defined by stringers of pyrrhotite.

Devonian to Mississippian Earn Group (DME) in this area consists of grey shales and black, thin bedded chert.

Mississippian Tay Formation (MT) conformably overlies Earn Group and comprises thin to medium beds of grey, silty limestone to calcareous siltstone between dark grey to black, variably quartz-rich siltstone to shale.

The youngest stratified rocks on the Property belong to Carboniferous to Permian Mount Christie Formation (CPMC), and consist of thin and medium bedded, maroon, black and grey-brown cherts.

A small Mid-Cretaceous Selwyn Suite pluton composed of light grey, medium grained, biotitehornblende granodiorite with megacrysts of feldspar up to 10 cm long cuts the sedimentary package two kilometres southwest of Keg Main Zone. No intrusive rocks have been observed on the Property.

A zone of pervasive hydrothermal alteration overprints sections of both Mount Christie Formation and Tay Formation on the Property. Within this alteration zone, rocks are commonly light grey to light pinkish-grey, massive and very fine-grained and host minor veinlets and disseminations of sulphide minerals. The alteration zone is approximately 3000 by 5000 m and is open along strike to the east and the west.

The fine grained nature of the rocks within and around the alteration zone makes mineral identification in hand sample difficult. As a result, Silver Range collected a suite a samples for

petrographic analyses in an attempt to better identify primary lithologies and alteration of rocks at Keg Main Zone and in surrounding areas. The following descriptions are based on observations made from petrographic examination of 56 samples from both drill core and outcrop using a microscope with both reflected light and refractive light capabilities. All minerals were identified using solely optical properties.

Three main lithologies were recognized in thin section - a chert that grades into very finegrained quartz dominated siltstone (Mount Christie Formation); a mildly siliceous mudstone (Tay Formation); and a calcareous siltstone made up of sub-angular quartz clasts cemented with calcite (Tay Formation).

Most samples show an early alteration assemblage comprising sericite $\pm$ carbonate $\pm$ silica that affects siliceous and calcareous sedimentary rocks in varying degrees, depending on host rock composition and proximity to structures.

Locally, a hydrothermal alteration assemblage overprints the sericite-carbonate-silica assemblage and can completely obliterate earlier rock textures. This alteration pattern is visible in hand sample and drill core as widespread bleaching and locally as vein-fill, fracture-fill and skarnification. In thin section, this assemblage comprises varying amounts of diaspora, andalusite, quartz, calcite, chloritoid, chalcedony, cordierite, staurolite, pyrophyllite, dumorierite and clays with rare corundum, plus sulphide minerals, including pyrrhotite, pyrite, sphalerite, chalcopyrite, galena and arsenopyrite. Pyrite-sphalerite-chalcopyrite-calcite $\pm$ staurolite $\pm$ andalusite $\pm$ corundum veins commonly have diaspore selvages. Andalusite veins clearly crosscut these multi-mineral veins. Chloritoid occurs in vein selvages and as pervasive disseminations throughout altered sections of rock within Keg Main Zone but is most abundant in distal parts of the alteration zone.

A later alteration event (possibly retrograde skarnification) comprising large bladed calcite crystals with pyrite and chalcopyrite occurs as clots or small lenses in a few drill core samples from Keg Main Zone. These clots overprint hydrothermal alteration described above.

Structural analysis of folded and thrusted areas of the Selwyn Basin depends on a sound understanding of stratigraphy. Fossil ages provided by Gordey (2008) were instrumental in the interpretation presented below. Nearly all of the dated fossil locations provided by Gordey (2008) were visited and have allowed for confident identification of most of the units described on the Property.

Several east-southeast trending thrust faults dip to the south and imbricate the stratigraphy in this area. An early thrust fault (Two Pete Thrust) places Rabbitkettle Formation on top of Ordovician to Mississippian stratigraphy (Gordey, 2008). This thrust fault does not appear to daylight within the Property due to several southeast trending normal faults that drop the stratigraphy down to the south (Figure 8). A more northerly situated thrust fault places Tay Formation over Mount Christie Formation. Locally this fault diverges into two parallel thrust faults: one placing Tay Formation over Mount Christie Formation and the other placing Earn and Road River Groups over Tay Formation.

North of the most northerly thrust fault Mount Christie Formation chert is tightly folded into cylindrical, metre-scale folds that commonly show moderately southwest-dipping limbs and steep to overturned, southwest- and northeast- dipping limbs (Figure 8). These folds are observed on metre and smaller scale throughout a canyon along Ivan Creek and in hill-top outcrops. The folds consistently plunge shallowly to moderately to the east-southeast and are interpreted to be parasitic to a regional antiform-synform pair trending northwest-southeast.

The regional faults and folds described in the previous paragraph are cut by many late, brittle faults that complicate map patterns and drill sections. Some of these features are shown on Figure 6, while others are too small or too poorly understood to include.

The canyon that runs along Ivan Creek provides excellent exposure of several late, brittle fault zones, which are up to five metres in width and comprise shattered chert fragments, milled rock and clay. Similar faults, characterized by clasts of quartz cemented by calcite, were observed in outcrop on a south facing slope east of the canyon. These faults dominantly strike east to southeast and dip moderately to steeply to the south. They are interpreted to be linked to normal faulting in the area.

Fracture and vein orientations in and around the Keg Main Area are broadly grouped into two sets. One set dips very steeply to the west and strikes south-southeast and the other dips subvertically north and strikes west. Both sets commonly contain sulphide minerals in veins and fractures, but the west striking set is more abundant but has finer fractures.

### 8.0 MINERALIZATION

Keg Main Zone comes to surface along the north side of an east-west trending ridge west of Ivan Creek. Keg East Zone is on a lower, parallel ridge east of the creek. Outcrop is rare within the zones - three relatively large, steep, gossanous talus slopes, containing scattered outcrops, are exposed near the centre of the Keg Main Zone, but other exposures are very small and isolated.

Mineralization has been found in talus and outcrop described above, within bedrock exposed in historical bulldozer trenches about 500 m west of Keg Main Zone and in drill core at both zones. Few rock samples have been collected at surface due to the relative lack of bedrock exposures and difficulty taking representative samples across the broad weathered talus slopes (Figure 6 shows the location of surface mineralization and Section 6.0 discusses assay results). Drill core provides more reliable data concerning the types and relative abundances of mineralization and more accurate dimensions and grades of the mineralized zones (see Section 10.0 for drill results).

Mineralization within Keg Main Zone is controlled by a combination of structure and stratigraphy within strongly hydrothermally altered and locally skarnified limestone and siltstone of Tay and/or Mount Christie Formations (Figure 6). Intense silicification of these formations makes it difficult to determine which unit is the primary host. The structural control is typified by fracture-fillings, while the stratigraphic control is characterized by disseminations to semimassive mineralization within calc-silicate altered, limey horizons. Sphalerite, chalcopyrite and galena occur in varying amounts with pyrrhotite, pyrite and arsenopyrite and rare stannite. The sulphide minerals are generally coarse grained. They typically comprise 1 to $10 \%$ of the rock,
often increasing to between 20 and $50 \%$ over metre-scale intervals within skarnified horizons. A general zonation has been observed with pyrrhotite and chalcopyrite dominating the sulphide assemblage in the deeper and western parts of the zone and galena contents higher in the upper and eastern parts. The western and central parts of the mineralized zone are notably depleted of calcium relative to the adjacent wall rocks, but calcite gangue is common in veins within the eastern part of the zone. The variations in relative sulphide abundance and gangue minerals are interpreted to indicate the deeper and western parts of the zone are more proximal to the core of the hydrothermal cell and the upper and eastern parts are more distal.

Mineralization at Keg East Zone is generally similar to that observed within the eastern part of the Keg Main Zone and is likely part of the same mineralizing system. Several features, including the presence of calcite gangue, lower pyrrhotite and chalcopyrite contents, and high silver to lead ratios, suggest that Keg East Zone is in a more distal setting than Keg Main Zone.

### 9.0 EXPLORATION

### 9.1 Geological Mapping

A description of geological mapping performed by Silver Range in 2011 and 2012 is provided in Section 7.0. Little or no geological mapping was reported by previous claim owners in the area. Mapping was limited in many areas by the absence of bedrock exposure.

### 9.2 Soil Geochemical Sampling

In 1973, Yukon Copper Ltd. completed grid soil sampling within some areas covered by the current Property. This work identified a strong, largely coincident copper $\pm$ lead $\pm$ zinc anomaly that extends east to west over the length of the Property. The anomaly reaches a maximum width of 1000 m. From 2010 to 2012, Strategic Metals and Silver Range re-sampled much of this area to confirm the tenor and extent of the historical anomaly and to obtain multi-element data.

From 2010 to 2012, a total of 1700 grid soil samples were collected at 50 m spacings along north-south oriented lines located 100 m apart within a 5000 by 2000 m grid. Soil sampling methods and analytical techniques are described in Sections 11.1 and 11.3, respectively. Effectiveness of soil sampling was limited in many areas by thick overburden, poor soil development and/or pervasive permafrost. Vegetated, north-facing slopes are typically blanketed by thick layers of organic material and are the most affected by permafrost. Despite these limitations, soil sampling appears to be the most effective surface exploration technique for identifying drill targets on the Property due to the paucity of bedrock exposures.

Keg Main Anomaly is defined by a high concentration of moderately to very strongly elevated values for silver, lead, zinc, copper, tin and indium, while Keg East Anomaly is a smaller, slightly weaker extension of it. Collectively, these anomalies comprise the five kilometre long by one kilometre wide Keg Anomaly, which is surrounded by a halo of weak values for all elements of interest except indium. Results for silver, lead, zinc, copper, tin and indium are illustrated thematically on Figures 9 to 14, while Table 9-1 lists the anomalous thresholds and peak values for these elements.

Table 9-1: Geochemical Data for Soil Samples

| Element | Anomalous Thresholds |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  | Weak | Moderate | Strong | Very Strong | Peak |
| Silver $(\mathrm{ppm})$ | $\geq 1<2$ | $\geq 2<5$ | $\geq 5<10$ | $\geq 10$ | 166 |
| Lead $(\mathrm{ppm})$ | $\geq 100<200$ | $\geq 200<500$ | $\geq 500<1000$ | $\geq 1000$ | 10200 |
| Zinc $(\mathrm{ppm})$ | $\geq 200<500$ | $\geq 500<1000$ | $\geq 1000<2000$ | $\geq 2000$ | 9370 |
| Copper $(\mathrm{ppm})$ | $\geq 50<100$ | $\geq 100<200$ | $\geq 200<500$ | $\geq 500$ | 4760 |
| Tin (ppm) | $\geq 5<10$ | $\geq 10<20$ | $\geq 20<50$ | $\geq 50$ | $>500^{*}$ |
| Indium $(\mathrm{ppm})$ | $\geq 1<2$ | $\geq 2<5$ | $\geq 5<10$ | $\geq 10$ | 40.8 |

* Not analyzed for over detection limit value.

Keg Anomaly exhibits a slight metal zonation from west to east. Copper is concentrated within the western and central parts of the anomaly, while indium is clustered in the centre and silver, lead, zinc and tin are most abundant in the east and central parts.

### 9.3 Geophysical Surveys

Between 1966 and 1977, several airborne and ground geophysical surveys (electromagnetic (EM), magnetic, induced polarization (IP) and gravity) were completed within the bounds of the current Property. Data from pre-2010 surveys was not available in digital format and therefore could not be reprocessed. Where data is available, historical magnetic and electromagnetic results generally support more recent data.

In 2010, Strategic Metals' commissioned Geotech Ltd. of Aurora, Ontario to fly a helicopterborne Z-axis Tipper Electromagnetic (ZTEM) and magnetic survey over the entire Property and Aurora Geosciences of Whitehorse, Yukon to perform ground IP surveying across parts of Keg Main Zone. In 2011, Aurora Geosciences completed additional ground IP surveying at the Keg Main and Keg East Zones on behalf of Silver Range. Only the 2010 and 2011 geophysical data is discussed in this report.

Condor Consulting, Inc. of Lakewood, Colorado was commissioned to process and analysis of the 2010 and 2011 geophysical data. Figures 15 and 16 show the magnetic and ZTEM results, along with locations of the IP survey lines, soil anomalies and diamond drill holes. Figure 17 illustrates a cross-section of modelled resistivity and conductivity from the IP survey. Geophysical results from both years are briefly summarized in the following paragraphs.

The magnetic response is diverse but generally reflects the regional, northwest-oriented geological and structural trends. A discrete magnetic high is locally coincident with an electromagnetic feature in the vicinity of Keg Main Zone. Condor does not consider the magnetic data to be a useful tool for direct targeting of mineralization; however, because it highlights structural and lithological features, it can be used to identify favourable mineralization traps.

The ZTEM data also shows a variety of responses, which also typically conform to the northwest regional fabric. Northwest-trending axial highs and areas of low response are both present on the Property. The highs likely represent parts of the stratigraphy that are more conductive. A

distinct, discrete conductive feature in the eastern half of the property may represent a largescale fold. The lows are interpreted as more resistive areas within the mapped units. These lows may represent hydrothermal silicification of the host rocks.

Condor deemed the most significant IP-resistivity features within Keg Main Zone to be coincident conductivity and chargeability highs that coincides with mineralization in the western half of the Keg Main Zone drill grid and in another area about 500 m north of Keg Main Zone. The first of these features appears to continue at least 500 m southwest of the drill grid, after which is either terminates or plunges to a depth beyond the detection limits of the survey. Scout drilling in the vicinity of the westerly highs intersected thick sections of rock containing abundant pyrrhotite on fractures, while holes that tested the northerly highs cut graphitic stratigraphy.

A secondary feature defined by elevated chargeability and moderate conductivity lies to the south of, and directly below, Keg Main Zone. This feature locally coincides with mineralized drill intervals (Figure 17).

### 10.0 DRILLING

### 10.1 Historical Diamond Drilling

Between 1966 and 1975, a total of nine drill holes were completed on ground currently covered by the Property. Grades and widths obtained from that drilling at Keg Main and Keg East Zones were considered to be disappointing by previous operators, because their target was massive stratiform mineralization like that in nearby deposits of the Anvil District. Wide intercepts of fracture-style mineralization and occasional skarn horizons were cut within Keg Main and Keg East Zones, but grade continuity was not established due to poor recovery caused by small core diameter (mostly AQ) and intermittent sampling of mineralized intervals (see Section 6.0 for results).

### 10.2 2010, 2011 and 2012 Diamond Drilling

The mineral resource presented in this report was determined using only data from diamond drilling completed between 2010 and 2012 within Keg Main Zone by Silver Range and Strategic Metals. Figures 18 and 19 illustrate the locations of all holes drilled on the Property from 2010 to 2012 (details of which holes were included in the mineral resource are provided in Section 14.0 - Mineral Resource Estimate).

Between 2010 and 2012, a total of 23,014.51 m of exploration and definition drilling in 69 holes was completed on the Property, of which $18,376.81 \mathrm{~m}$ in 53 holes was used to estimate the Keg Main Zone mineral resource. Down hole depths for drill holes used in the mineral resource estimation range from 144.00 to 550.77 m , with an average depth of 359.30 m . This drilling was completed at nominal 100 m spacings on an 1100 m long by 300 m wide grid (locally up to 450 m wide, see Figure 18) within the main area of interest. All holes were collared at dips of $50^{\circ}$ and most of them are on section lines oriented at $340^{\circ}$ (north-northwest). Six holes have different azimuth orientations, which range between $300^{\circ}$ and $010^{\circ}$ (northwest to north-

northeast). The number of holes and total meterages drilled on the Property each year between 2010 and 2012 are listed by zone in Table 10-1.

Table 10-1: 2010 to 2012 Diamond Drilling Summary

| Target - Year | Holes Drilled | Total Drilled (m) |
| :--- | :---: | :---: |
| Keg Main Zone - 2010 | 4 | 958.27 |
| Keg Main Zone - 2011 | 26 | 10350.82 |
| Keg Main Zone - 2012 | 21 | 7014.99 |
| Keg Main Zone - Abandoned $*$ | 3 | 72.73 |
| Keg East Zone $-2011 / 2012 *$ | 11 | 3245.68 |
| Scout Exploration $-2011 / 2012^{*}$ | 4 | 1372.02 |

* Not included in mineral resource estimate.

Relatively continuous silver-lead-zinc-copper-tin $\pm$ indium mineralization has been traced along the full 1100 m length of the drill grid, across approximate true widths of 50 to 250 m and to vertical depths of 350 m . Examples of this geometry are illustrated on Figures 20 and 21.

Descriptions of mineralization intersected at both Keg Main and Keg East Zones are provided in Section 8.0. The best grades within both zones are typically from areas where strong fracturing and reactive horizons coincide. The thickest, highest grade mineralization within Keg Main Zone appears to be localized in a fold hinge where axial planar fractures cut silicified and calcsilicate altered Tay and Mount Christie Formation rocks.

The most significant, silver-rich interval obtained from Keg Main Zone to date graded $70.55 \mathrm{~g} / \mathrm{t}$ silver, $0.54 \%$ lead, $0.60 \%$ zinc, $0.17 \%$ copper, 778 ppm tin and 1.77 ppm indium over 104.70 m from 25.45 to 130.15 m in hole KEG-11-009. The best 2012 interval averaged $63.45 \mathrm{~g} / \mathrm{t}$ silver, $0.48 \%$ lead, $0.43 \%$ zinc, $0.09 \%$ copper, 448 ppm tin and 0.96 ppm indium over 68.75 m from 6.64 to 75.39 m in hole KEG-12-047. Table 10-2 lists highlight drill results obtained from Keg Main Zone.

Table 10-2: Highlight Keg Main Zone Drill Results

| Hole No. | From (m) | $\begin{gathered} \text { To } \\ \text { (m) } \end{gathered}$ | Interval (m) | $\begin{gathered} \mathrm{Ag} \\ (\mathrm{~g} / \mathrm{t}) \end{gathered}$ | $\begin{gathered} \hline \mathbf{P b} \\ (\%) \\ \hline \end{gathered}$ | $\begin{gathered} \mathrm{Zn} \\ (\%) \\ \hline \end{gathered}$ | $\begin{gathered} \mathrm{Cu} \\ (\%) \\ \hline \end{gathered}$ | $\begin{gathered} \text { Sn } \\ (\mathrm{ppm}) \end{gathered}$ | $\begin{gathered} \text { In } \\ (\mathrm{ppm}) \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The best interval from Keg East Zone graded $30.81 \mathrm{~g} / \mathrm{t}$ silver, $0.18 \%$ lead, $0.27 \%$ zinc, $0.02 \%$ copper, 65 ppm tin and 1.01 ppm indium over 70.11 m from 302.36 to 372.47 m in hole KEG-11-014. The best 2012 result averaged $31.89 \mathrm{~g} / \mathrm{t}$ silver, $0.39 \%$ lead, $0.33 \%$ zinc, $0.01 \%$ copper, 278 ppm tin and 0.51 ppm indium over 13.4 m from 74.00 to 87.40 m in hole KEG-12-059. None of the holes from Keg East Zone are included in the mineral resource estimate.

The Author does not know of any drilling, sampling or recovery factors that could materially impact the accuracy and reliability of the 2010 to 2012 drill results.

### 10.3 Diamond Drilling Specifications

All 2010 to 2012 diamond drilling on the Property was conducted by Top Rank Diamond Drilling Ltd. of Ste. Rose du Lac, Manitoba.

The 2010 work was done with a heli-portable, diesel-powered JKS-300 drill using HQ and BTW equipment. The 2011 and 2012 holes were completed by two heli-portable Multi-Power Discovery II drills using NQ2 equipment.

### 10.4 Drill Collar and Down-Hole Surveys

All drill hole collars were surveyed by Archer Cathro employees using a Trimble SPS882 and SPS852 base and rover Real Time Kinematic (RTK) GPS system. The collars are marked by lengths of drill rod that are cemented into the holes. A metal tag identifying the hole number is affixed to each rod.

Topography along section lines was initially surveyed by chain and compass, but was later resurveyed using the RTK GPS.

Down-hole surveys were conducted using a "Ranger Explorer" magnetic multi-shot tool provided by Ranger Survey Systems. Shots were taken every 50 feet or 15 m in each hole, depending on whether the rods were imperial or metric. The shots recorded azimuth, inclination, temperature, roll angle (gravity and magnetic) plus magnetic intensity, magnetic dip and gravity intensity (for quality assurance). All readings were reviewed and erroneous data were not used when plotting the final hole traces.

### 11.0 SAMPLE PREPARATION, SECURITY AND ANALYSIS

This section describes the sampling methods, sample handling, analytical techniques and security measures followed during the 2010 to 2012 exploration programs. The programs were supervised by Archer Cathro on behalf of Strategic Metals and Silver Range.

The methods and approaches, where available, in the pre-2010 historical reports were reviewed. Those reports were prepared prior to the implementation of NI 43-101 and although the methods applied were industry standard at the time, the reports do not meet the standards of NI 43-101.

### 11.1 Sampling Methods

In 2010, 2011 and 2012, grid soil samples were collected at 50 m intervals along north-south oriented lines spaced 100 m apart. All soil sample locations were recorded using hand-held GPS units. Sample sites are marked by aluminum tags inscribed with the sample numbers and affixed to 0.5 m wooden lath that were driven into the ground. Soil samples were collected from 10 to 80 cm deep holes using hand-held augers. They were placed into individually pre-numbered Kraft paper bags. Sampling was often hindered by permafrost on moss-covered, north-facing slopes. Samples were not collected from many of these locations due to poor sample quality. Very few rock samples were collected form the Keg Main or Keg East Zones, because there are limited bedrock exposures and exploration progressed rapidly to diamond drilling, which largely negated the usefulness of less representative rock samples.

Geotechnical and geological logging was performed on all drill core from the 2010 to 2012 programs. A geotechnical log was filled out prior to geological logging of drill core and included the conversion, where needed, of drill marker blocks from imperial to metric and determinations of recovery, rock quality designations (RQD), hardness and weathering. Wetted core photographs were taken and catalogued prior to logging.

A sample was collected every six boxes for density measurements using both wet and dry evaluation methods to provide base level density data for resource evaluation. Magnetic susceptibility measurements were taken at one metre intervals along each hole.

All logging data were recorded as a hardcopy during the day and transcribed to digital format during the evenings.

Drill core samples were collected using the following procedures:

1) Core was reassembled, lightly washed and measured.
2) Core was photographed.
3) Core was geotechnically logged.
4) Core was geologically logged and sample intervals were designated. Sample intervals were set at geological boundaries, drill blocks or sharp changes in sulphide content.
5) Core recovery was calculated for each sample interval.
6) In 2010, visually promising core intervals were sawn in half using a rock saw and the remainder was split with an impact core splitter. In 2011 and 2012, all core was sawn in half. One-half was sent for analysis and one-half returned to the core box.
7) Samples were double bagged in 6 mm plastic bags, a sample tag was placed in each sample bag, then two or three samples were placed in a fiberglass bag sealed with a metal clasp and sample numbers were written on the outside of that bag with permanent felt pen. The fibreglass bag was sealed with a numbered security tag.
8) Two blank and two standard samples were randomly included in every batch of 31 core samples (in 2012, batches comprised 30 core samples).
9) One quarter-split duplicate sample was included in every batch of 31 core samples (in 2012, batches comprised 30 core samples).
10) In 2012, one coarse reject duplicate sample was included in every batch of 30 core samples.

Core recovery was good, averaging $96 \%$ for the 2010 to 2012 drill programs. The holes were mostly sampled top to bottom (about $90 \%$ of core was sampled). Care was taken to ensure that the sample split was not biased to sulphide content and, therefore, the sampling should be reliable and representative of the mineralization.

### 11.2 Sample Handling and Security

In 2010, the drill core was flown by helicopter from the drill sites to the company's staging area at the Faro airport, where it was transferred to a truck and transported to Whitehorse for logging and sampling. In 2011 and 2012, the core was flown by helicopter from the drill sites to a logging and sampling area on the Property. The samples were later flown by helicopter to the Faro staging area and transported to Whitehorse by truck. All samples were controlled by employees of Archer Cathro until they were delivered directly to ALS Minerals' laboratory in Whitehorse for preparation. ALS Minerals was responsible for shipping the prepared sample splits to its North Vancouver laboratory, where they were analyzed.

Archer Cathro ensured that a Chain of Custody form accompanied all batches of drill core during transportation from the Property to the laboratory. A unique security tag was attached to each individual fibreglass bag when the bag was sealed. The bags and security tags had to be intact in order to be delivered to ALS Minerals.

### 11.3 Sample Analysis

All samples were sent to ALS Minerals' laboratory in Whitehorse for preparation and then on to its laboratory in North Vancouver for analysis. ALS Minerals, a wholly owned subsidiary of ALS Limited, is an independent commercial laboratory specializing in analytical geochemistry services. Both ALS Minerals' Whitehorse and North Vancouver laboratories are individually certified to standards within ISO 9001:2008. The North Vancouver laboratory has also received accreditation to ISO/IEC 17025:2005 from the Standards Council of Canada for several analytical methods.

All 2010 to 2012 soil samples were dried and screened to -180 microns. The 2010 soil samples were analyzed for 35 elements by aqua regia digestion followed by inductively coupled plasma with atomic emission spectroscopy (ME-ICP41). An additional 30 g charge was further analyzed for gold by fire assay with inductively coupled plasma-atomic emissions spectroscopy finish (Au-ICP21). The samples were reanalyzed for 51 elements by aqua regia digestion followed by inductively coupled plasma combined with mass spectroscopy or atomic emission spectroscopy (ME-MS41).

The 2011 soil samples were analyzed for 51 elements using aqua regia digestion followed by inductively coupled plasma combined with mass spectroscopy or atomic emission spectroscopy (ME-MS41). Soil samples were further analyzed for gold by aqua regia digestion followed by inductively coupled mass spectrometry (Au-TL43).

The 2012 soil samples were analyzed for 51 elements using aqua regia digestion followed by inductively coupled plasma combined with mass spectroscopy or atomic emission spectroscopy (ME-MS41). An additional 30 g charge was further analyzed for gold by fire assay with inductively coupled plasma-atomic emissions spectroscopy finish (Au-ICP21).

All 2010 to 2012 rock and core samples were dried, fine crushed to better than $70 \%$ passing -2 mm and then a 250 g split was pulverized to better than $85 \%$ passing 75 microns.

The 2010 rock and core samples were initially analyzed for gold by fire assay followed by atomic absorption (Au-AA24) and 35 other elements using aqua regia digestion followed by inductively coupled plasma-atomic emission spectroscopy (ME-ICP41). Samples in mineralized intervals were later assayed for silver, zinc, lead and copper ( $\mathrm{Ag} / \mathrm{Zn} / \mathrm{Pb} / \mathrm{Cu}-\mathrm{OG} 62$ ); geochemically analyzed for 51 elements (which include common refractory elements) by aqua regia digestion followed by inductively coupled plasma combined with mass spectroscopy or atomic emission spectroscopy (ME-MS41); and analyzed for tin and tungsten by pressed pellet XRF (Sn/W-XRF05).

The 2011 rock and core samples were analyzed for 51 elements by aqua regia digestion followed by inductively coupled plasma combined with mass spectroscopy or atomic emission spectroscopy (ME-MS41) and tin using pressed pellet XRF (Sn-XRF05). Samples that exceeded upper detection limits were assayed for silver, zinc, lead and/or copper by $\mathrm{Ag} / \mathrm{Zn} / \mathrm{Pb} / \mathrm{Cu}-\mathrm{OG} 46$. From the beginning of the program until late July, the core samples were analyzed for gold by aqua regia and mass spectroscopy (Au-TL44). During the QA/QC review, there were difficulties reproducing gold values from standard samples analyzed by this technique. These difficulties, combined with more severe problems encountered using the Au-TL44 technique on other projects with higher gold contents (conducted by another company managed by Archer Cathro) lead Silver Range to change techniques. The difficulties involved understatement of gold contents. For the remainder of the program, the core samples were analyzed for gold by fire assay followed by atomic absorption (Au-AA24).

The 2012 rock and core samples were routinely analyzed for gold by fire assay followed by atomic absorption (Au-AA24), tin using pressed pellet XRF (Sn-XRF05) and for 48 other elements using four acid digestion followed by inductively coupled plasma-mass spectroscopy
(ME-MS61). Samples in mineralized intervals that exceeded the upper detection limits were assayed for silver, zinc, lead and copper by inductively coupled plasma-atomic emission spectroscopy ( $\mathrm{Ag} / \mathrm{Pb} / \mathrm{Zn} / \mathrm{Cu}-\mathrm{OG} 62$ ).

All 2010 to 2012 standard, blank and duplicate samples passed QA/QC reviews. It is the Author's opinion that the sample preparation, security and analytical procedures used for this project are adequate.

### 12.0 DATA VERIFICATION

### 12.1 Database

Geological and geotechnical logging prior to 2012 was initially recorded as a hardcopy and then transcribed into MS Excel ${ }^{\circledR}$. In 2012, logging was recorded as a hardcopy and then entered into a MS SQL Server ${ }^{\circledR}$ database. All of the pre-2012 data has been transferred to the database.

Visual comparison of hardcopy data and digital data was conducted on select holes to ensure accuracy. Any discrepancies identified by this process were investigated, by examining the core stored on the Property, and corrected.

### 12.2 Collar Locations

All drill hole collars were re-surveyed in 2012 using a Trimble RTK GPS system and, where necessary, survey data collected in previous years was corrected. The differences between this most recent survey and the earlier surveys can be explained by the poorer accuracy of the hand held equipment used in previous years.

The collar data stored in the MS SQL Server ${ }^{\circledR}$ database have been visually cross-checked with the digital survey reports generated by the Trimble system. No errors were found.

### 12.3 Down-hole Orientations

Prior to 2011, no down-hole azimuth measurements were made and dip deviations were measured using an acid test at the bottom of each hole. This practice does not follow industry standards, but due to the limited number of holes (four) and shallow depths (all but one less than 255 m ), the Author does not consider this to be a significant issue.

Original 2011 and 2012 survey data obtained from the survey tools in CSV format has been imported directly into the MS SQL Server ${ }^{\circledR}$ database. All of the down-hole data was visually inspected and erroneous data has been omitted.

### 12.4 Assays

Assay certificates, for all of the drilling done to date, were obtained from ALS Minerals in CSV format and imported directly into the MS SQL Server ${ }^{\circledR}$ database. Spot checking of data within the database to hard copy certificates issued by ALS Minerals has not revealed any issues.

Samples from the diamond drilling programs were subjected to a QA/QC program designed by Archer Cathro for Silver Range. The QA/QC program consisted of:

1) Sequentially numbered sample tickets: to identify each sample with a unique number to minimize the possibility of sample numbering errors and to ensure uniform collection of sample data.
2) Sealed sample bags: to secure individual sample bags in order to reduce the possibility of sample contamination, spilling or tampering.
3) Chain of custody: samples were stored in a secure preparation area and delivered to the laboratory directly by Archer Cathro personnel.
4) Sample duplicates: select samples were quartered and re-submitted for assay. In addition, duplicates of coarse reject material of select 2012 samples were re-submitted for assay.
5) Sample blanks: commercial samples were purchased and inserted in the sample sequence. All blank samples yielded background values, including samples inserted directly following a "standard" value to test for "smear effect" during the sample preparation process, indicating no observable contamination. These blanks were assigned unique sample numbers within the sample sequence so as to be "blind" to the laboratory.
6) Reference standard samples: commercially available standard samples for silver, copper, lead and zinc were purchased for the 2010 and 2011 drill program. Four standards were prepared from coarse reject material from the 2011 core samples for use during the 2012 drill program. Standards were assigned a unique sample number within the sample sequence.

All of the samples have passed this QA/QC program. It is the Author's opinion that the assay results contained within the database are suitable for use in a resource estimation.

### 13.0 MINERAL PROCESSING AND METALLURGICAL TESTING

### 13.1 Introduction

Metallurgical testwork on the Keg Main Zone was completed at SGS Canada Inc. Lakefield Research located in Lakefield Ontario in 2012. Melis Engineering Ltd. (Melis) of Saskatchewan directed and summarized the metallurgical testwork on behalf of Silver Range. This testwork was directed by Lawrence Melis, P.Eng., who is a qualified person and independent of both the issuer and the title holder, based on the tests outlined in National Instrument 43-101. Melis' full report is provided in Appendix I.

The testwork was completed on six variability composites representing distinct zones of the known mineralization and one overall composite prepared as a blend of the six variability composites. The work encompassed preparation and analyses of test composites, comminution testing, open cycle and lock cycle flotation tests, gravity recovery tests, concentrate analyses and tailings physical and chemical characterization.

### 13.2 Composite Analyses

Key analyses of the test composites are summarized in Table 13-1.
Table 13-1: Test Composites - Assay Head Grades for Key Elements

| Composite | Ag (g/t) | $\mathbf{C u}(\%)$ | Pb (\%) | Zn (\%) | In (g/t) | Sn (g/t) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Overall | 41.6 | 0.27 | 0.31 | 1.36 | 11.4 | 400 |
| A | 89.1 | 0.18 | 0.62 | 0.69 | 1.7 | 770 |
| B | 56.2 | 0.60 | 0.30 | 2.30 | 15.6 | 760 |
| C | 44.1 | 0.31 | 0.34 | 1.67 | 13.1 | 230 |
| D | 32.3 | 0.10 | 0.27 | 0.89 | 8.8 | 100 |
| E | 21.1 | 0.14 | 0.15 | 1.28 | 19.5 | 210 |
| F | 32.7 | 0.19 | 0.28 | 1.14 | 9.1 | 360 |

The sulphides in the mineralization consist mainly of sphalerite, pyrite, chalcopyrite, pyrrhotite, galena and arsenopyrite. Traces of silver minerals (native silver and silver sulphides) were found, but more detailed examination specific to silver would be required to properly define the mode of occurrence of silver. The main tin minerals, which are typically fine grained, include stannite and lesser cassiterite.

A gravity recovery test on the overall composite indicated that approximately $15 \%$ of the silver and only about $3 \%$ of the tin could be recoverable by gravity.

Preliminary grinding tests suggest that the Keg Main Zone mineralization is of medium hardness.

### 13.3 Flotation Testwork

A total of 16 open cycle batch flotation tests were completed on the overall composite to identify the flotation characteristics of Keg Main Zone mineralization and to quantify optimum flotation parameters for the recovery of copper, lead and zinc to concentrates. Six open cycle batch flotation tests were also completed on the six variability composites, one per composite to assess variability ahead of lock cycle testing.

The flotation conditions and reagent scheme identified for the mineralization were generally as follows:

- Target primary grind $\mathrm{P}_{80}$ of $100 \mu \mathrm{~m}$ in the presence of lime to maintain pH 8 to 8.5.
- Copper/lead rougher flotation at pH 9 to 9.5 controlled with lime using Aerophine 3418A as collector and MIBC as frother.
- Regrind of the copper/lead rougher concentrate to a target $\mathrm{P}_{80}$ of 20 to $25 \mu \mathrm{~m}$ in the presence of zinc sulphate and sodium cyanide used as zinc depressant, additional lime to maintain an elevated pH and additional 3418A collector.
- Three stages of copper/lead cleaners at pH 10 controlled with lime with further 3418A collector addition and MIBC frother.
- Copper/lead separation on the third copper/lead cleaner concentrate at pH 11 in the presence of sodium cyanide with additional 3418A collector and MIBC frother, followed by one cleaning stage at pH 11 with further addition of sodium cyanide, 3418A collector and MIBC frother to produce an upgraded lead concentrate. The rougher tails from the copper/lead separation float constitute the copper concentrate.
- The copper/lead rougher tails and the copper/lead first cleaner tails, feed to the zinc rougher float, are conditioned at pH 11.8 adjusted with lime in the presence of copper sulphate activator.
- Zinc rougher flotation using Aero 5100 as collector with further lime addition to maintain pH 11.8 and further MIBC frother addition.
- Regrind of the zinc rougher concentrate to a target $\mathrm{P}_{80}$ of 15 to $20 \mu \mathrm{~m}$ in the presence of additional copper sulphate activator and additional lime to maintain pH 12 .
- The reground zinc rougher concentrate was submitted to four zinc cleaning stages with further additions of lime to maintain pH 12 , and further Aero 5100 collector addition. The use of sodium metabisulphite ( NaMBS ) in the zinc cleaners improved the zinc grade to the final zinc cleaner concentrate.

### 13.4 Results of Lock Cycle Tests

A total of eight lock cycle tests were completed to quantify recoveries and concentrate grades for Keg Main Zone mineralization under conditions approaching steady state. Results are summarized in Table 13-2.

Table 13-2: Summary of Lock Cycle Test Results

| Composite | A | B | C | D | E | F | Avg. | Overall | Overall |  |

| Average | 1.33 | 0.33 | 0.25 | 45.9 | 11.3 | 88.6 | 82.4 | 69.4 | 80.0 | 82.9 |
| Overall | 1.36 | 0.31 | 0.27 | 41.6 | 11.4 | 85.2 | 84.8 | 71.4 | 82.5 | 80.1 |
| Overall NaMBS | 1.36 | 0.31 | 0.27 | 41.6 | 11.4 | 87.7 | 86.0 | 69.2 | 83.4 | 85.5 |

Notes: 1. Combined silver recovery to lead and copper concentrate
2. Combined indium recovery to zinc and copper concentrate

The results of the lock cycle tests on all test composites show that Keg Main Zone mineralization responds very well to typical copper/lead/zinc flotation circuits with excellent recoveries of payable metals and acceptable copper, lead and zinc concentrate grades in
copper, lead and zinc concentrates. General comments and observations on the lock cycle results include the following:

- There was generally good agreement between the results of the Overall Composite and the average results of the six variability composites, both with respect to grades and recoveries.
- Zinc concentrate grades of greater than $45 \%$ zinc were achievable on composites with head grades greater than $1.0 \%$ zinc. The use of sodium metabisulphite (NaMBS) in the zinc cleaner circuit leads to a higher zinc grade in the zinc concentrate (approaching 50\% zinc) without impacting on zinc recovery.
- The lead grade in the lead concentrate, which averaged $65 \%$ lead, was independent of the head grade of the composites. Excellent lead concentrate grades were achieved even down to a low head grade of $0.15 \%$ lead. The lower lead concentrate grade in the lead concentrate from the last lock cycle test $(59.4 \%$ lead versus $65.5 \%$ lead in the first lock cycle test) was due to an increase in cleaner flotation time in the copper/lead cleaner float, which pulled more weight to the third copper/lead cleaner concentrate and impacted on copper/lead separation.
- Excellent copper grades were obtained in the copper concentrate, averaging 27.2\% copper, even for the composites with relatively low copper head grade.
- Zinc recoveries to zinc concentrate averaged $88.6 \%$ and were generally over $90 \%$ for composites with zinc head grades greater than $1.0 \%$ zinc.
- Lead recoveries to lead concentrate averaged $82.4 \%$ and were all greater than $80 \%$ except for the one composite with a low lead head grade which had a $77.5 \%$ lead recovery for a $0.15 \%$ lead head grade, still quite acceptable for a low head grade.
- Copper recoveries averaged $69.4 \%$ and generally followed copper head grade, ranging from $80.2 \%$ recovery for a $0.60 \%$ copper head grade to $59.0 \%$ for a $0.10 \%$ copper head grade.
- Excellent silver recoveries were achieved, averaging 57.2\% recovery to lead concentrate assaying an average of $5,816 \mathrm{~g} / \mathrm{t}$ silver, and $22.7 \%$ recovery to copper concentrate assaying an average of $1,458 \mathrm{~g} / \mathrm{t}$ silver. A minor amount, an average of $8.2 \%$, reported to the zinc concentrate which assayed an average of $136 \mathrm{~g} / \mathrm{t}$ silver. Silver head grade did not have much impact on overall silver recovery.
- The majority of the recoverable indium reported to the zinc concentrate, averaging $74.3 \%$ recovery and assaying an average of $320 \mathrm{~g} / \mathrm{t}$ indium. A lesser amount, $8.6 \%$, was recovered to the copper concentrate assaying an average of $150 \mathrm{~g} / \mathrm{t}$ indium. No indium reported to the lead concentrate. Indium head grade did not seem to have an impact on overall indium recovery.
- The average tin grades were $1.99 \%$ tin in the copper concentrate, $0.44 \%$ tin in the lead concentrate and $0.04 \%$ in the zinc concentrate. The majority of the tin, an average of $60 \%$, was not recovered and reported to the final float tails which had an average tails tin assay of $0.025 \%$ tin.

### 13.5 Concentrate Analyses

Key analyses of the copper, lead and zinc concentrates, composites of the concentrates from the six cycles (A-F) of the lock cycle tests, are summarized in Table 13-4. These analyses
can be used as preliminary data in marketing studies and for developing smelter terms for each concentrate.

Table 13-4: Lock Cycle Tests - Key Analyses of Concentrates

| Element | Unit | Overall Comp. | Comp A | Comp B | Comp C | Comp D | Comp E | Comp F |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

A static settling test was completed on the zinc flotation tailings from Test LCT1. This test showed that a thickened tailings density of $69 \%$ solids ( $\mathrm{w} / \mathrm{w}$ ) could be achieved using a feed pulp density of $10 \%$ solids ( $\mathrm{w} / \mathrm{w}$ ) and a Magnafloc 10 flocculant dosage of $8 \mathrm{~g} / \mathrm{t}$. Allowing for a $25 \%$ design factor the thickener unit area was measured at $0.10 \mathrm{~m}^{2} / \mathrm{t} /$ day implying that the Keg Main Zone flotation tailings settle relatively well.

### 14.0 MINERAL RESOURCE ESTIMATE

### 14.1 Introduction

Silver Range contracted Giroux Consultants Ltd. to complete a mineral resource estimate on the Keg Main Zone. The mineral resource was estimated by Gary Giroux, P.Eng., MASc. who is a qualified person and independent of both the issuer and the title holder, based on the tests outlined in National Instrument 43-101.

The database supplied for this mineral resource has an effective date of October 1, 2012 and contained information on 69 diamond drill holes. A list of drill holes provided is contained in Appendix II.

### 14.2 Data Analysis

A geologic solid was provided by Matthew Dumala, P.Eng. from Archer Cathro. Keg Main Zone comprises a system of structurally and stratigraphically controlled mineralization within a package of strongly hydrothermally altered and locally skarnified limestone and siltstone. The geologic model focused on defining the upper and lower boundaries of the mineralized zone. Mineralization occurs almost everywhere within this zone; however, much of it is pyrrhotite and not economical. The thickest, highest grade mineralization appears to be localized in a fold hinge where axial planar fractures cut this package (north edge of the deposit, near surface). Of particular interest is a higher grade silver and lead zone that occurs at or near surface on the northern edge of the drill area and is almost entirely fracture controlled. This silver and lead rich zone outcrops in places.

Drill holes were "passed through" this geologic solid with the entry and exit points recorded. Using this information the assays were "back tagged" with a code of MIN if inside the solid
and WASTE if outside. Of the 69 supplied drill holes, 53 holes totalling 18,377 m intersected the mineralized solid (See Appendix II - Holes intersecting the mineralized solid are highlighted). Figure 22 shows the drill holes in plan view with samples within the mineralized solid shown in magenta, while Figure 23 provides an isometric view looking southwest at the mineralized solid, drill hole traces and surface topography.

Figure 22 - Plan view showing drill hole traces with samples within mineralized solid in magenta

Figure 23 - Isometric view looking SW showing mineralized solid, drill hole traces and surface topography

Statistics for the raw assay data are listed below in Table 14-1 for the mineralized solid and for the surrounding waste.

Table 14-1: Assays within the Mineralized Solid and Waste

|  | Ag <br> (g/t) | Pb <br> (\%) | Zn <br> $\mathbf{( \% )}$ | Cu <br> (\%) | Sn <br> (ppm) | In <br> (ppm) | Cd <br> (ppm) |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Within Mineralized Solid (Using 4385 Samples) |  |  |  |  |  |  |  |
| Mean grade | 15.66 | 0.15 | 0.55 | 0.09 | 159.2 | 4.82 | 96.49 |
| Standard deviation | 46.21 | 0.52 | 1.32 | 0.22 | 362.7 | 12.62 | 189.09 |
| Minimum value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum value | 1230.0 | 9.3 | 17.5 | 4.8 | 10400 | 320 | 1000 |
| Coefficient of variation | 2.95 | 3.58 | 2.42 | 2.37 | 2.28 | 2.62 | 1.96 |
| Waste (Using 3684 Samples) |  |  |  |  |  |  |  |
| Mean grade | 2.54 | 0.02 | 0.06 | 0.01 | 52.5 | 0.26 | 10.42 |
| Standard deviation | 8.95 | 0.12 | 0.22 | 0.03 | 95.7 | 1.00 | 35.63 |
| Minimum value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum value | 158.0 | 2.9 | 5.7 | 1.0 | 2600 | 28 | 801 |
| Coefficient of variation | 3.52 | 4.94 | 3.44 | 2.23 | 1.82 | 3.92 | 3.42 |

To determine if capping was required and if so at what level, the grade distributions for each variable in each domain were examined using lognormal cumulative frequency plots. The procedure used is explained in a paper by Dr. A.J. Sinclair (1976) titled "Applications of probability graphs in mineral exploration." In short, the cumulative distribution of a single normal distribution will plot as a straight line on probability paper while a single lognormal distribution will plot as a straight line on lognormal probability paper. Overlapping populations will plot as curves separated by inflection points. Sinclair proposed a method of separating out these overlapping populations using a technique called partitioning. In 1993, a computer program called P-RES was made available to partition probability plots interactively on a computer (Bentzen and Sinclair, 1993). A screen dump from this program is shown for silver within the mineralized zone in Figure 24. The actual data distribution is shown as black dots. The inflection points that separate the populations are shown as vertical lines and each population is shown by the straight lines of open circles. The interpretation is tested by recombining the data in the proportions selected and the test is shown as triangles compared to the original distribution. Each variable is examined in the following section with the populations broken out and thresholds selected for capping if required.

Figure 24 - Lognormal cumulative frequency plot for silver in mineralized solid
The plot shows six overlapping lognormal populations, as tabulated in Table 14-2.
Table 14-2: Silver Populations within the Mineralized Solid

| Population | Mean <br> Ag(g/t) | Percentage of <br> Total Data | Number of <br> Assays |
| :---: | :---: | :---: | :---: |
| 1 | 1134.0 | $0.05 \%$ | 2 |
| 2 | 273.9 | $1.10 \%$ | 48 |
| 3 | 51.3 | $13.63 \%$ | 598 |
| 4 | 6.9 | $36.55 \%$ | 1603 |
| 5 | 0.6 | $48.49 \%$ | 2126 |
| 6 | 0.02 | $0.18 \%$ | 8 |

Population 1 representing $0.05 \%$ of the total samples was considered erratic outlier material and a value of two standard deviations above the mean of Population 2 was used to cap three assays at $576 \mathrm{~g} / \mathrm{t}$ silver. A similar procedure was used for the other six elements within the mineralized zone and all seven variables within waste. The cap levels are summarized in Table 14-3.

Table 14-3: Capping Levels for all Variables within the Mineralized Solid and Waste

| Domain | Variable | Cap Level | Number <br> Capped |
| :---: | :---: | :---: | :---: |
| Mineralized Solid | Ag | $576 \mathrm{~g} / \mathrm{t}$ | 3 |
|  | Pb | $10.3 \%$ | 0 |
|  | Zn | $18.0 \%$ | 0 |
|  | Cu | $2.6 \%$ | 3 |
|  | Sn | 5280 ppm | 4 |
|  | In | 122 ppm | 3 |
|  | Cd | 1100 ppm | 0 |
|  | Ag | $64 \mathrm{~g} / \mathrm{t}$ | 16 |
|  | Pb | $1.3 \%$ | 7 |
|  | Zn | $2.4 \%$ | 7 |
|  | Cu | $0.3 \%$ | 7 |
|  | Sn | 1050 ppm | 3 |
|  | In | 10 ppm | 5 |
|  | Cd | 310 ppm | 8 |

The results of capping are shown in Table 14-4.
Table 14-4: Capped Assays within the Mineralized Solid and Waste

|  | Ag <br> (g/t) | Pb <br> $\mathbf{( \% )}$ | Zn <br> $\mathbf{( \% )}$ | Cu <br> $\mathbf{( \% )}$ | Sn <br> ppm | In <br> ppm | Cd <br> Ppm |
| :--- | ---: | :---: | ---: | ---: | ---: | ---: | ---: |
| Within Mineralized Solid (Using 4385 Samples) |  |  |  |  |  |  |  |
| Mean Grade | 15.40 | 0.15 | 0.55 | 0.09 | 157.1 | 4.75 | 96.49 |
| Standard Deviation | 41.42 | 0.52 | 1.32 | 0.20 | 320.8 | 11.52 | 189.09 |
| Minimum Value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum Value | 576.0 | 9.3 | 17.5 | 2.6 | 5280.0 | 122 | 1000 |
| Coefficient of Variation | 2.69 | 3.58 | 2.42 | 2.22 | 2.04 | 2.42 | 1.96 |
| Waste (Using $\mathbf{3 6 8 4}$ Samples) |  |  |  |  |  |  |  |
| Mean Grade | 2.32 | 0.02 | 0.06 | 0.01 | 51.8 | 0.24 | 9.80 |
| Standard Deviation | 6.14 | 0.09 | 0.17 | 0.02 | 83.0 | 0.78 | 26.17 |
| Minimum Value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum Value | 64.0 | 1.3 | 2.4 | 0.3 | 1050 | 10 | 310 |
| Coefficient of Variation | 2.65 | 3.84 | 2.72 | 1.76 | 1.60 | 3.22 | 2.67 |

### 14.3 Composites

Uniform down hole composites, 5 m in length, were produced to honour the mineralized solid. Intervals at the solid boundaries, less than 2.5 m in length, were combined with adjoining samples to produce a uniform support of $5 \pm 2.5 \mathrm{~m}$. Composites were also produced for areas outside the mineralized solid in areas considered waste. Unsampled
intervals at the tops and bottoms of holes were set to low values and used to produce the waste composites. Table 14-5 shows the statistics for both sets of 5 m composites.

Table 14-5: Five Metre Composites within the Mineralized Solid and Waste

|  | $\begin{gathered} \mathbf{A g} \\ (\mathrm{g} / \mathrm{t}) \end{gathered}$ | $\begin{gathered} \text { Pb } \\ (\%) \end{gathered}$ | $\begin{gathered} \mathrm{Zn} \\ (\%) \end{gathered}$ | $\begin{gathered} \mathrm{Cu} \\ (\%) \\ \hline \end{gathered}$ | Sn ppm | $\begin{gathered} \text { In } \\ \text { ppm } \end{gathered}$ | $\begin{gathered} \text { Cd } \\ \text { Ppm } \\ \hline \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Within Mineralized Solid (Using 2202 Samples) |  |  |  |  |  |  |  |
| Mean Grade | 10.42 | 0.10 | 0.36 | 0.07 | 124.3 | 3.15 | 65.72 |
| Standard Deviation | 21.92 | 0.25 | 0.66 | 0.11 | 204.8 | 6.21 | 110.24 |
| Minimum Value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum Value | 273.9 | 3.3 | 10.2 | 1.5 | 2471.7 | 57.9 | 812.2 |
| Coefficient of Variation | 2.10 | 2.59 | 1.83 | 1.66 | 1.65 | 1.97 | 1.68 |
| Waste (Using 2394 Samples) |  |  |  |  |  |  |  |
| Mean Grade | 1.81 | 0.02 | 0.05 | 0.01 | 44.2 | 0.19 | 7.74 |
| Standard Deviation | 3.73 | 0.04 | 0.10 | 0.02 | 64.9 | 0.49 | 15.72 |
| Minimum Value | 0.01 | 0.001 | 0.001 | 0.001 | 0.1 | 0.003 | 0.01 |
| Maximum Value | 54.0 | 0.5 | 1.3 | 0.2 | 903.4 | 6.9 | 193.3 |
| Coefficient of Variation | 2.06 | 2.54 | 1.99 | 1.45 | 1.47 | 2.59 | 2.03 |

As all variables showed a strongly positive skewed grade distribution, a Pearson correlation matrix was generated for variables within the mineralized zone from log transformed values. The correlation matrix is provided in Table 14-6.

Table 14-6: Pearson Correlation Coefficients

|  | $\mathbf{A g}$ | $\mathbf{P b}$ | $\mathbf{Z n}$ | $\mathbf{C u}$ | $\mathbf{S n}$ | $\mathbf{I n}$ | $\mathbf{C d}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{A g}$ (g/t) | 1.0000 |  |  |  |  |  |  |
| $\mathbf{P b}$ (\%) | 0.9098 | 1.0000 |  |  |  |  |  |
| $\mathbf{Z n}$ (\%) | 0.8359 | 0.7118 | 1.0000 |  |  |  |  |
| $\mathbf{C u}$ (\%) | 0.6397 | 0.3743 | 0.6883 | 1.0000 |  |  |  |
| Sn (ppm) | 0.8529 | 0.7525 | 0.7604 | 0.5706 | 1.0000 |  |  |
| In (ppm) | 0.7408 | 0.5662 | 0.9461 | 0.7013 | 0.6733 | 1.0000 |  |
| $\mathbf{C d}$ (ppm) | 0.8330 | 0.6883 | 0.9891 | 0.6879 | 0.7787 | 0.9468 | 1.0000 |

In general, there is reasonable correlation between all variables but there is an excellent correlation (greater than 90 ) between silver-lead, zinc-indium, zinc-cadmium and indiumcadmium and good correlation (greater than .70) between silver-zinc, silver-tin, silverindium, silver-cadmium, lead-zinc, lead-tin, zinc-tin, copper-indium and tin-cadmium.

### 14.4 Variography

Pairwise relative semivariograms were used to model each variable within the mineralized solid. The down hole direction was modeled first to establish the nugget effect and sill levels. A geometric anisotropy was identified in all cases with the two longest directions of continuity along strike at azimuth $75^{\circ}$ and plunging $-15^{\circ}$ to the east and down dip at azimuth
$345^{\circ}$ dipping $-50^{\circ}$. The third direction along azimuth $165^{\circ}$ dipping $-40^{\circ}$ had no sample pairs closer than 50 m so a short range was assumed. The high correlation between variables is reflected in the variography, with all models similar in shape and overall distances. The nugget to sill ratio, a reflection of the sample variability, was quite reasonable ranging from a low of $20 \%$ for indium to a high of $37.5 \%$ for lead.

For waste material a single isotropic nested model was fit to all variables with the longest range a constant 180 m .

The models are summarized below in Table 14-7 and shown in Appendix III.
Table 14-7: Semivariogram Parameters

| Domain | Variable | $\mathrm{C}_{0}$ | $\mathrm{C}_{1}$ | $\mathrm{C}_{2}$ | Az/Dip | Ranges (m) | Az/Dip | Ranges (m) | Az/Dip | Ranges (m) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Mineralized Solid | Ag | 0.24 | 0.28 | 0.18 | 75/-15 | 35-120 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | Pb | 0.30 | 0.34 | 0.16 | 75/-15 | 30-120 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | Zn | 0.30 | 0.31 | 0.20 | 75/-15 | 45-130 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | Cu | 0.15 | 0.20 | 0.08 | 75/-15 | 25-120 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | Sn | 0.10 | 0.30 | 0.10 | 75/-15 | 40-120 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | In | 0.30 | 0.35 | 0.24 | 75/-15 | 40-120 | 345/-50 | 25-100 | 165/-40 | 15-40 |
|  | Cd | 0.32 | 0.33 | 0.24 | 75/-15 | 50-100 | 345/-50 | 25-100 | 165/-40 | 15-40 |
| Waste | Ag | 0.25 | 0.30 | 0.31 | Omni Directional |  |  | 25-180 |  |  |
|  | Pb | 0.30 | 0.30 | 0.30 | Omni Directional |  |  | 25-180 |  |  |
|  | Zn | 0.28 | 0.30 | 0.36 | Omni Directional |  |  | 25-180 |  |  |
|  | Cu | 0.14 | 0.20 | 0.29 | Omni Directional |  |  | 32-180 |  |  |
|  | Sn | 0.14 | 0.30 | 0.26 | Omni Directional |  |  | 26-180 |  |  |
|  | In | 0.30 | 0.30 | 0.47 | Omni Directional |  |  | 30-180 |  |  |
|  | Cd | 0.30 | 0.38 | 0.32 | Omni Directional |  |  | 25-180 |  |  |

### 14.5 Block Model

A block model with blocks $20 \times 20 \times 5 \mathrm{~m}$ in dimension was built to cover the mineralized solid. Within each block the percentage below surface topography and the percentage within the mineralized solid were recorded. The block model origin is described below and Figure 25 provides an isometric view looking north of the blocks (in white) and mineralized composites (in magenta).

Figure 25 - Isometric view looking North showing blocks in white and mineralized composites in magenta

### 14.6 Bulk Density

The bulk density for rock at Keg Main Zone was established from 907 specific gravity determinations made from pieces of drill core using the weight in air - weight in water procedure. The results are shown in Appendix IV and the results are summarized as a function of rock type in Table 14-8.

Table 14-8: Specific Gravity Determinations Sorted by Rock Type

| Rock Type | Number | Minimum | Maximum | Average |
| :---: | :---: | :---: | :---: | :---: |
| ARG | 46 | 2.38 | 2.87 | 2.66 |
| CGL | 5 | 2.62 | 3.64 | 2.86 |
| CHT | 29 | 2.48 | 3.51 | 2.81 |
| CSL | 3 | 2.63 | 2.92 | 2.75 |
| FLR | 14 | 2.31 | 2.74 | 2.59 |
| ICL | 425 | 1.84 | 3.59 | 2.76 |
| LST | 50 | 2.22 | 3.07 | 2.71 |
| MET | 7 | 2.49 | 2.73 | 2.60 |
| OVB | 1 |  |  | 2.68 |

| SLA | 2 |  |  | 2.65 |
| :---: | ---: | ---: | ---: | ---: |
| SLM | 1 |  |  | 2.59 |
| SLT | 252 | 2.29 | 3.30 | 2.71 |
| SSS | 72 | 2.33 | 3.23 | 2.73 |
| Total | $\mathbf{9 0 7}$ | $\mathbf{1 . 8 4}$ | $\mathbf{3 . 6 4}$ | $\mathbf{2 . 7 3}$ |

As can be seen from Table 14-8 there is a wide range of specific gravities in most of the rock types and the specific gravity of any given sample is more a function of sulphide content than host rock type. As a result, a specific gravity value was interpolated into each block in the model using the inversed distance squared procedure.

### 14.7 Grade Interpolation

Grades for silver, lead, zinc, copper, tin, indium and cadmium were interpolated into blocks within the mineralized solid using Ordinary Kriging. The kriging exercise was completed in a series of four passes with the search ellipse for each pass determined by the range of the semivariogram in each of the three principal directions. In the first pass the search ellipse dimensions were set to one quarter of the semivariogram range and a minimum of four composites were required to estimate a block. For blocks not estimated in Pass 1 a second pass was completed expanding the search ellipse to half the semivariogram range. Again a minimum of four composites were required to estimate the block. A third pass using the full range and a fourth pass using twice the range completed the kriging exercise. In all cases the maximum number of composites used was set to 12 with a maximum of three composites allowed from any given drill hole. This insured that each block was estimated using a minimum of two drill holes.

For all estimated blocks with some percentage outside the mineralized solid, in waste, a similar exercise was completed using only composites outside the mineralized solid. In this manner the edge dilution was determined for estimated blocks from actual assays.

Finally for all estimated blocks a specific gravity value was estimated using Inverse Distance Squared interpolation.

The search parameters and number of blocks estimated in each pass are shown in Table 14-9 for silver.

Table 14-9: Kriging Search Parameters for Silver

| Domain | Pass | Number <br> Estimated | Az/Dip | Dist. <br> $(\mathbf{m})$ | Az/Dip | Dist. <br> $(\mathbf{m})$ | Az/Dip | Dist. <br> $(\mathbf{m})$ |
| :---: | :---: | :---: | :---: | ---: | :---: | ---: | ---: | :---: |
| Ag in <br> Mineralized <br> Solid | 1 | 119 | $75^{\circ} /-15^{\circ}$ | 30.0 | $345^{\circ} /-50^{\circ}$ | 25.0 | $165^{\circ} /-40^{\circ}$ | 10.0 |
|  | 2 | 1,577 | $75^{\circ} /-15^{\circ}$ | 60.0 | $345^{\circ} /-50^{\circ}$ | 50.0 | $165^{\circ}-40^{\circ}$ | 20.0 |
|  | 3 | 26,736 | $75^{\circ} /-15^{\circ}$ | 120.0 | $345^{\circ} /-50^{\circ}$ | 100.0 | $165^{\circ} /-40^{\circ}$ | 40.0 |
|  | 4 | 23,344 | $75^{\circ} /-15^{\circ}$ | 240.0 | $345^{\circ} /-50^{\circ}$ | 200.0 | $165^{\circ} /-40^{\circ}$ | 80.0 |
| Ag in | 1 | 574 | Omni Directional |  | 45.0 |  |  |  |
|  | 2 | 4,746 | Omni Directional |  |  |  |  |  |

|  | 3 | 3,196 | Omni Directional | 180.0 |  |  |
| :--- | ---: | ---: | :--- | ---: | ---: | ---: |
|  | 4 | 125 | Omni Directional | 360.0 |  |  |

### 14.8 Classification

Based on the study herein reported, delineated mineralization of Keg Main Zone is classified as a mineral resource according to the following definitions from National Instrument 43101 and from CIM (2005):
"In this Instrument, the terms "mineral resource", "inferred mineral resource", "indicated mineral resource" and "measured mineral resource" have the meanings ascribed to those terms by the Canadian Institute of Mining, Metallurgy and Petroleum, as the CIM Definition Standards on Mineral Resources and Mineral Reserves adopted by CIM Council, as those definitions may be amended."

The terms Measured, Indicated and Inferred are defined by CIM (2005) as follows:
"A Mineral Resource is a concentration or occurrence of diamonds, natural solid inorganic material, or natural solid fossilized organic material including base and precious metals, coal and industrial minerals in or on the Earth's crust in such form and quantity and of such a grade or quality that it has reasonable prospects for economic extraction. The location, quantity, grade, geological characteristics and continuity of a Mineral Resource are known, estimated or interpreted from specific geological evidence and knowledge."
"The term Mineral Resource covers mineralization and natural material of intrinsic economic interest which has been identified and estimated through exploration and sampling and within which Mineral Reserves may subsequently be defined by the consideration and application of technical, economic, legal, environmental, socio-economic and governmental factors. The phrase 'reasonable prospects for economic extraction' implies a judgment by the Qualified Person in respect of the technical and economic factors likely to influence the prospect of economic extraction. A Mineral Resource is an inventory of mineralization that under realistically assumed and justifiable technical and economic conditions might become economically extractable. These assumptions must be presented explicitly in both public and technical reports."

## Inferred Mineral Resource

"An 'Inferred Mineral Resource' is that part of a Mineral Resource for which quantity and grade or quality can be estimated on the basis of geological evidence and limited sampling and reasonably assumed, but not verified, geological and grade continuity. The estimate is based on limited information and sampling gathered through appropriate techniques from locations such as outcrops, trenches, workings and drill holes."
"Due to the uncertainty that may be attached to Inferred Mineral Resources, it cannot be assumed that all or any part of an Inferred Mineral Resource will be upgraded to an Indicated or Measured Mineral Resource as a result of continued exploration. Confidence in the estimate is insufficient to allow the meaningful application of technical and economic
parameters or to enable an evaluation of economic viability worthy of public disclosure. Inferred Mineral Resources must be excluded from estimates forming the basis of feasibility or other economic studies."

## Indicated Mineral Resource

"An 'Indicated Mineral Resource’ is that part of a Mineral Resource for which quantity, grade or quality, densities, shape and physical characteristics, can be estimated with a level of confidence sufficient to allow the appropriate application of technical and economic parameters, to support mine planning and evaluation of the economic viability of the deposit. The estimate is based on detailed and reliable exploration and testing information gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes that are spaced closely enough for geological and grade continuity to be reasonably assumed."
"Mineralization may be classified as an Indicated Mineral Resource by the Qualified Person when the nature, quality, quantity and distribution of data are such as to allow confident interpretation of the geological framework and to reasonably assume the continuity of mineralization. The Qualified Person must recognize the importance of the Indicated Mineral Resource category to the advancement of the feasibility of the project. An Indicated Mineral Resource estimate is of sufficient quality to support a Preliminary Feasibility Study which can serve as the basis for major development decisions."

Within the Property surface mapping and drill hole interpretation was used to establish the limits of the mineralized solid and hence geologic continuity. Grade continuity can be quantified by semivariogram analysis. By orienting the search ellipse in the directions of maximum continuity, as established by variography, the grade continuity can be utilized to classify the resource.

In more developed properties, blocks estimated in Pass 1 using one quarter of the semivariogram range might be considered measured, while those estimated in Pass 2 using half the range might be indicated. In the case of Keg Main Zone, the drill hole spacing is still too coarse to classify any of this mineral resource as measured or indicated. Table 14-9 shows that only three percent of the blocks were estimated in Passes 1 and 2. As a result, all blocks are considered inferred at this time.

Table 14-10 shows the mineral resource estimated if one could mine to the limits of the mineralized solid. This mineral resource contains only the mineralized portions of blocks. A silver cut-off grade of $16 \mathrm{~g} / \mathrm{t}$ is highlighted as a possible open pit cut-off grade, although at this time no economic evaluation has been completed.

Table 14-10: Inferred Mineral Resource within Mineralized Solid

| Cut-off$(\mathbf{A g} g / t)$ | $\begin{gathered} \text { Tonnes > } \\ \text { Cut-off } \\ \text { (tonnes) } \\ \hline \end{gathered}$ | Grade > Cut-off |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 14.9 Model Verification

In order to verify the block model results, two methods were used: swath plots and cross sections.

Swath plots take slices through the mineral deposit comparing average grades of blocks with the average grades of composites. The results are shown for east-west slices (Figure 26), for north-south slices (Figure 27) and for slices in the vertical plane (Figure 28). In general, the block estimates match very well with the sample grades with the larger deviations occurring in areas with few sample points. The north-south plot shows pronounced zonation with the grades for both samples and blocks increasing systematically from south to north.

Figure 26 - Swath plot for Keg Main Zone 40 m East-West slices

Figure 27 - Swath plot for Keg Main Zone 40 m North-South slices

Figure 28 - Swath plot for Keg Main Zone 20 m vertical slices

In addition to swath plots a set of west looking, north-south cross sections was produced where estimated block grades were compared to composite grades. There was no bias indicated, with results matching raw data well. Figures 29 to 32 show example north-south cross sections. The drill hole composites are shown are within a 50 m swath on either side of the blocks.

Figure 29 - Section 586850 E showing estimated blocks and composites

Figure 30 - Section 586650 E showing estimated blocks and composites

Figure 31 - Section 586450 E showing estimated blocks and composites

Figure 32 - Section 586250 E showing estimated blocks and composites

### 15.0 DEPOSIT TYPES

Keg Main Zone comprises a large-scale, low grade, multi-element mineralized system that is being explored as a bulk tonnage target. It is located 25 km north of the former mines of the Anvil District, which comprised concordant and syngenetic sedimentary exhalative zinc-leadsilver deposits that are further described in Section 16.0. Keg Main Zone differs from the deposits of the Anvil District because it is predominantly discordant, epigenetic and lower grade. Keg Main Zone has an atypical metal suite and, although it is believed to be hydrothermal in origin, the deposit is located some distance from the closest known intrusion.

There are no known deposits that are directly analogous to Keg Main Zone. Table 15-1 lists the average grades of the mineral resources from some significant, multi-element, bulk tonnage deposits in comparison to Keg Main Zone.

Table 15-1: Comparison of Keg Main Zone with Multi-Metal, Bulk-Tonnage Deposits

| Deposit/ Prospect | $\underset{(\mathrm{g} / \mathrm{t})}{\mathrm{Ag}}$ | $\underset{(\mathrm{g} / \mathrm{t})}{\mathrm{Au}}$ | $\begin{array}{r} \mathrm{Zn} \\ (\%) \end{array}$ | $\begin{gathered} \text { Pb } \\ (\%) \end{gathered}$ | $\begin{gathered} \mathrm{Cu} \\ (\%) \end{gathered}$ | $\begin{gathered} \text { Sn } \\ \text { (ppm) } \end{gathered}$ | $\begin{gathered} \text { In } \\ (\text { ppm }) \end{gathered}$ | Reserve Resource (Mt) | Notes |

${ }^{3}$ Capstone Mining Corp., 2012
${ }^{4}$ Thompson Creek Metals Company Inc., 2012
${ }^{5}$ Armitage et al, 2011
Keg Main Zone lies in the Northern Cordillera, which hosts numerous low grade, bulk tonnage deposits, including Capstone Mining Corp.'s Minto Mine and Thompson Creek Metals Company Inc.'s Mt. Milligan Deposit. The Minto Mine, located in central Yukon, is a copper-gold-silver open pit mine that commenced production in 2007. Its deposit type is also uncertain, but it has attributes of porphyry copper, magnetite skarn and Iron Oxide Copper Gold (IOCG) deposits.

The Mt. Milligan porphyry copper-gold deposit is located in central British Columbia and is under construction as an open pit mine, which is expected to be operating in 2013.

The most similar of the listed deposits in terms of size and grade is Kootenay Silver Inc.'s Promontorio Deposit in northwest Mexico. This deposit comprises a carbonate-rich, diatremehosted, polymetallic silver-lead-zinc deposit.

South American Silver Corp.'s Malku Khota deposit in Bolivia appears to be the most analogous to Keg Main Zone in terms of geochemistry and possible genesis. Like Keg Main Zone, early exploration in the Malku Khota area focussed on high grade stratabound sulphide lenses within clastic sedimentary units. These lenses were likely associated with Jurassic and Cretaceous rift development. A later hydrothermal event related to a hypothesized intrusive-hosted gold system brought minor gold with new and redistributed silver, lead, zinc, copper, indium and gallium mineralization into the clastic rocks. The mineralized zone is up to 200 m in true width and is at least four kilometres long.

Keg Main Zone is distinguished from these other bulk tonnage deposits by its uncommonly high tin values.

### 16.0 ADJACENT PROPERTIES

The Property is part of a larger, contiguous claim block known as the Silver Range Project. The Silver Range Project consists of a total of 4,744 mineral claims that are wholly owned by Silver Range.

The Silver Range Project hosts 24 primary zones of surface mineralization (including the Keg and Keg East Zones) that lie within two parallel, northwest-trending belts. The Tay Belt is the more northerly of the two and covers a 60 by 5 km area that is mainly characterized by mesothermal, fracture-filling and skarn/replacement style mineralization. The Mount Mye Belt is located 15 km south of Tay Belt and 12 km northeast of the former Faro Mine and mill site. It comprises mesothermal and epithermal mineralization that is mostly hosted in veins and fracture zones. Figure 33 shows the locations of the mineralized zones on the Silver Range Project.

Although Silver Range's primary focus is the Keg Main Zone, its exploration programs encompass the entire Silver Range Project and have included regional and detailed scale soil sampling, detailed prospecting, geological mapping, ground and airborne geophysical surveys, reverse circulation drilling and diamond drilling.

The Faro mill site processed ores from three of the five known sedimentary exhalative zinc-leadsilver deposits within the Anvil District, which is located 25 km south of Keg Main Zone (Figure 33). This style of mineralization has not been identified on the Property.

The three deposits (Vangorda, Faro and Grum) were mined intermittently between 1969 and January 1998. The other two deposits (Grizzly and Swim) were not developed because the operations went into receivership during a period of prolonged low metal prices in the 1990s. The combined pre-mining historical mineral resource estimate for deposits in the belt was 120

Mt grading $5.6 \%$ zinc, $3.7 \%$ lead and 45 to $50 \mathrm{~g} / \mathrm{t}$ silver (Yukon Mining, 2011). At their peak, the mines of the Anvil District were collectively the world's third largest zinc producer. As of December 31, 1996, the Grum deposit was estimated to contain a historical resource of 18.64 Mt grading $4.43 \%$ zinc, $2.68 \%$ lead, $45 \mathrm{~g} / \mathrm{t}$ silver and $0.75 \mathrm{~g} / \mathrm{t}$ gold (Deklerk and Traynor, 2005). Together, the Grizzly and Swim deposits contain a historical resource estimate of 17.24 Mt grading $6.39 \%$ zinc, $4.85 \%$ lead, $71.6 \mathrm{~g} / \mathrm{t}$ silver and $0.75 \mathrm{~g} / \mathrm{t}$ gold and 4.3 Mt grading $4.7 \%$ zinc, $3.8 \%$ lead and $42 \mathrm{~g} / \mathrm{t}$ silver, respectively (Yukon Mining, 2008).

While it is believed that the resource estimates of the Anvil Range met or exceeded industry best practices at the time they were estimated; no recent work is known to have been performed to bring these resources to current standards.

The Faro mine site - including disused buildings, tailings, Vangorda, Faro and Grum pits and undeveloped Grizzly and Swim deposits - is held under receivership by the Government of Canada and part of the area is withdrawn from staking. The site is under care and maintenance and is subject to reclamation.

### 17.0 OTHER RELEVANT DATA AND INFORMATION

### 17.1 Environmental Studies

Environmental monitoring on the Property commenced in 2010 and includes ongoing baseline water quality and wildlife surveys.

The water quality surveys are being performed by J. Gibson Environmental Consulting of Whitehorse. Since August 2010, several sites on the Property have been sampled on a quarterly basis but, as of October 2012, sampling frequency was increased to monthly. The samples are analyzed for routine chemistry, total metals, dissolved metals, total organic carbon, total cyanide and mercury plus field measurements for pH , water temperature and flow volumes.

In summer 2011 and winter 2011-2012, wildlife surveys were conducted on the property by Laberge Environmental Services of Whitehorse, Yukon. Additional surveys are planned.

In November 2012, a base station for monitoring climate was set up on the Property, near the Keg Main Zone.

### 17.2 Heritage Studies

In May 2012, Matrix Resources Ltd. performed a preliminary heritage resources overview assessment for the Property. Detailed ground follow-up is planned for summer 2013.

### 17.3 Access Route Studies

In November 2012, EBA Engineering Consultants Ltd. was contracted to evaluate potential routes for an all-season access route from the old Faro mill site to Keg Main Zone. Results of this evaluation are not yet complete.

### 18.0 INTERPRETATION AND CONCLUSIONS

Keg Main Zone is a bulk-tonnage silver-lead-zinc-copper $\pm$ tin $\pm$ indium deposit situated north of the formerly producing Anvil Zinc-Lead-Silver District. The inferred mineral resource for the Keg Main Zone deposit comprises $39,760,000 \mathrm{t}$ grading $30.25 \mathrm{~g} / \mathrm{t}$ silver, $0.26 \%$ lead, $0.77 \%$ zinc, $0.15 \%$ copper, 265.7 ppm tin, 5.77 ppm indium and 138.06 ppm cadmium. This resource is stated above a $16.0 \mathrm{~g} / \mathrm{t}$ silver cut-off grade.

The deposit is distinguished from other large base metal showings and deposits elsewhere in Yukon by its uncommonly high silver contents relative to contained base metals and by its enrichments of tin, indium and other relatively rare metals. Metallurgical testwork has demonstrated that flotation processing can effectively recover most of the silver, copper, zinc, lead and indium. Tin recovery is poor.

Keg Main Zone is favourably situated in an area where several regional structural elements occur close together. This cluster of large-scale structures likely played an important role in ground
preparation for the deposit. The mineralization is hosted in strongly altered and folded siliceous siltstone and chert, which may have been deformed by a buried thrust fault that failed to break through these units. During folding of siliceous siltstone and chert, small scale fracturing produced permeability in the otherwise relatively impermeable rocks.

In addition to the ground preparation described above other elements probably played roles in the development of mineralization within Keg Main Zone. The folded and fractured siliceous siltstone and chert are interbedded with silty limestone and calcareous siltstone, which are the most reactive rocks in the area. Fluids channeling through the fractured siliceous siltstone and chert likely flowed upwards or laterally into the reactive stratigraphy. A small intrusive plug located approximately two kilometres south of the deposit may have provided a local heat source that powered at the mineralizing hydrothermal cell. Late normal and dip-slip faults crosscut the folded siliceous siltstone and chert and may have acted as deep-seated fluid conduits that localized hydrothermal flow.

Exploration conducted to date at Keg Main Zone has defined a sizeable mineral resource, and metallurgical testwork has produced encouraging results. Keg Main Zone is very well situated in regards to infrastructure. Further work is warranted.

### 19.0 RECOMMENDATIONS

Silver Range should conduct: a scoping level economic evaluation; additional diamond drilling targeted at better defining and expanding the Keg Main Zone mineral resource; further metallurgical testwork; and additional geotechnical, heritage and environmental studies.

Infill diamond drilling should be completed to upgrade the mineral resource from inferred to indicated or measured. Drilling should also be conducted to determine whether the deposit can be extended further to depth and/or along strike. Larger diameter drill core should be used in some holes to aid in additional metallurgical testwork, and oriented drill core should be obtained to provide data to support preliminary pit slope design for conceptual pit walls.

A Preliminary Economic Assessment has been initiated and evaluation of road access routes is being done. Current environmental and heritage base line studies should continue, and piezometers should be installed for ground water monitoring.

An approximate budget for this work totals $\$ 3,946,800$ as presented in Table 19-1.
Table 19-1: Proposed Budget for 2013 Exploration at Keg Main Zone

| Work Type | Cost (\$) |
| :--- | :---: |
| Diamond drilling (5000 m at \$150/m including fuel, core <br> boxes, mob/demob) | 750,000 |
| Helicopter | 600,000 |
| Bulldozer | 30,000 |
| Assay \& Analytical | 150,000 |
| Labour | 300,000 |

| Expediting, Safety \& Accounting | 100,000 |
| :--- | ---: |
| Report Preparation \& Senior Supervision | 180,000 |
| Room \& Board | 225,000 |
| Airfares, Ground Transportation \& Shipping | 100,000 |
| Environmental \& Heritage Surveys | 250,000 |
| Metallurgical Testwork | 400,000 |
| Preliminary Economic Assessment | 220,000 |
| Road Route Assessment | 85,000 |
| Consultant's Management Fee | 198,000 |
| Contingency at 10\% | 358,800 |
| Total (excluding GST) | $3,946,800$ |

## 21.0

 CERTIFICATES OF AUTHORS
### 21.1 Certificate and Consent of G.H. Giroux

I, G.H. Giroux, of North Vancouver, British Columbia do hereby certify that:

1) I am a consulting geological engineer with an office at 1215 - 675 West Hastings Street, Vancouver, British Columbia
2) I graduated from the University of British Columbia in 1970 with a B.A. Sc. and in 1984 with a M.A. Sc., both in Geological Engineering.
3) I am a member in good standing of the Association of Professional Engineers and Geoscientists of the Province of British Columbia.
4) I have practiced my profession continuously since 1970. I have over 30 years of experience calculating mineral resources. I have previously completed resource estimations on a variety of silver-lead-zinc deposits including the Wolverine, Keno Hill and Logan Deposits in Yukon.
5) I have read the definition of "qualified person" set out in NI 43-101 and certify that by reason of education, experience, independence and affiliation with a professional association, I meet the requirements of an independent Qualified Person as defined in NI 43-101.
6) I am responsible for the preparation of Sections 1.0 to 12.0 (excluding Section 1.3) and Sections 14.0 to 20.0 of the Technical Report titled "Technical Report describing Geology, Mineralization, Geochemical Surveys, Diamond Drilling, Metallurgical Testing and Mineral Resources at the Keg Property" and dated December 19, 2012 and amended on May 27, 2013. I visited the property on August $31^{\text {st }}$ and September 1st, 2011.
7) I have not previously worked on this deposit.
8) As of the date of this certificate, to the best of my knowledge, information and belief, the portion of the Technical Report for which I am responsible contains all scientific and technical information that is required to be disclosed to make that portion of the Technical Report not misleading.
9) I am independent of the issuer applying all of the tests in section 1.5 of NI 43-101.
10) I have read NI 43-101 and Form 43-101F1, and the Technical Report has been prepared in compliance with that instrument and form.
11) I consent to the public filing of the Technical Report with any stock exchange and other regulatory authority and its publication by them for regulatory purposes, including electronic publication in the public company files on their websites accessible by the public.

Dated this $27^{\text {th }}$ day of May, 2013.
(signed) G.H. Giroux
(sealed)
G.H. Giroux, P.Eng., MASc.

### 21.2 Certificate and Consent of L.A. Melis

I, Lawrence A. Melis, of 259 Egnatoff Cres., Saskatoon, Saskatchewan, do hereby certify that:

1) I am a consulting process engineer, working for Melis Engineering Ltd. with an office at 2366 Ave C North, Saskatoon, Saskatchewan, Canada.
2) I am a graduate of the University of Western Ontario in 1971 with a B.Sc. (Chemistry).
3) I am a member in good standing of the Association of Professional Engineers and Geoscientists of the Province of British Columbia (Registration No. 19398).
4) I have practiced my profession continuously since 1971. I have over 40 years of experience in process engineering for the mining industry.
5) I have read the definition of "qualified person" set out in National Instrument 43-101 and certify that by reason of education, experience, independence and affiliation with a professional association, I meet the requirements of an Independent Qualified Person as defined in National Instrument 43-101.
6) I am responsible for the preparation of Sections 1.3 and 13.0 of the Technical Report titled "Technical Report describing Geology, Mineralization, Geochemical Surveys, Diamond Drilling, Metallurgical Testing and Mineral Resources at the Keg Property" dated December 19, 2012 and amended on May 27, 2013.
7) I have not visited the property and have not previously worked on the project.
8) To the best of my knowledge, information and belief, Sections 1.3 and 13.0 of the Technical Report contain all scientific and technical information that is required to be disclosed to make the metallurgical component of the Technical Report not misleading.
9) I am independent of Silver Range Resources Ltd. as defined by National Instrument 43-101.
10) I have read NI 43-101 and Form 43-101F1, and Sections 1.3 and 13.0 of the Technical Report, for which I am responsible, has been prepared in compliance with that instrument and form.
11) I consent to the public filing of the Technical Report with any stock exchange and other regulatory authority and its publication by them for regulatory purposes, including electronic publication in the public company files on their websites accessible by the public.

Dated this $27^{\text {th }}$ day of May, 2013.

Re: Metallurgy Section of the December 2012 Silver Range Technical Report

Attached, please find the Melis Engineering Ltd. (Melis) report Silver Range Resources Ltd. Silver Range Project Keg Main Zone Yukon Canada Metallurgical Section of December 2012 Technical Report. It is provided as a Word file such that it can be extracted and used as Section 13 of the Technical Report.

This report summarizes results of metallurgical testwork completed at SGS Canada Inc. - Lakefield Research on test composites prepared from drill core of the Keg Main Zone deposit.

This report may be used as part of the 2012 Technical Report being prepared by Silver Range Resources Ltd. A summary section has been included in the report which can be extracted and used in the main body of the report, if preferred by Silver Range Resources Ltd., with the report in its entirety included as an appendix to the Technical Report.

Yours truly,
MELIS ENGINEERING LTD.
Lawrence Melis, P.Eng. President

### 13.1 SUMMARY

## Introduction

Metallurgical testwork on the Keg Main Zone of the Silver Range Project was completed at SGS Canada Inc. - Lakefield Research located in Lakefield Ontario in 2012.

The testwork was completed on six variability composites representing distinct zones of the known mineralization and one overall composite prepared as a blend of the six variability composites. The work encompassed preparation and analyses of test composites, comminution testing, open cycle and lock cycle flotation tests, gravity recovery tests, concentrate analyses and tailings physical and chemical characterization.

## Composite Analyses

Key analyses of the test composites are summarized in the table below.

| Silver Range Resources Ltd. - Keg Main Zone Metallurgical Testwork Test Composites - Assay Head Grades for Key Elements |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Composite | Ag, g/t | $\mathrm{Cu}, \%$ | Pb, \% | Zn, \% | In, g/t | Sn, g/t |
| Overall | 41.6 | 0.27 | 0.31 | 1.36 | 11.4 | 400 |
| A | 89.1 | 0.18 | 0.62 | 0.69 | 1.7 | 770 |
| B | 56.2 | 0.60 | 0.30 | 2.30 | 15.6 | 760 |
| C | 44.1 | 0.31 | 0.34 | 1.67 | 13.1 | 230 |
| D | 32.3 | 0.10 | 0.27 | 0.89 | 8.8 | 100 |
| E | 21.1 | 0.14 | 0.15 | 1.28 | 19.5 | 210 |
| F | 32.7 | 0.19 | 0.28 | 1.14 | 9.1 | 360 |

The sulphides in the mineralization consist mainly of sphalerite, pyrite, chalcopyrite, pyrrhotite, galena and arsenopyrite. Traces of silver minerals (native silver and silver sulphides) were found, but more detailed examination specific to silver would be required to properly define the mode of occurrence of silver. The main tin minerals, which are typically fine grained, include stannite and lesser cassiterite.

A gravity recovery test on the overall composite indicated that approximately $15 \%$ of the silver and only about $3 \%$ of the tin could be recoverable by gravity.

Preliminary grinding tests suggest that the Keg Main Zone mineralization is of medium hardness.

## Flotation Testwork

A total of 16 open cycle batch flotation tests were completed on the overall composite to identify the flotation characteristics of the Keg Main Zone mineralization and to quantify optimum flotation parameters for the recovery of copper, lead and zinc to concentrates. Six open cycle batch flotation tests were also completed on the six variability composites, one per composite to assess variability ahead of lock cycle testing.
The flotation conditions and reagent scheme identified for the mineralization were generally as follows:

- Target primary grind $\mathrm{P}_{80}$ of $100 \mu \mathrm{~m}$ in the presence of lime to maintain pH 8 to 8.5.
- Copper/lead rougher flotation at pH 9 to 9.5 controlled with lime using Aerophine 3418A as collector and MIBC as frother.
- Regrind of the copper/lead rougher concentrate to a target $\mathrm{P}_{80}$ of 20 to $25 \mu \mathrm{~m}$ in the presence of zinc sulphate and sodium cyanide used as zinc depressant, additional lime to maintain an elevated pH and additional 3418A collector.
- Three stages of copper/lead cleaners at pH 10 controlled with lime with further 3418A collector addition and MIBC frother.
- Copper/lead separation on the third copper/lead cleaner concentrate at pH 11 in the presence of sodium cyanide with additional 3418A collector and MIBC frother, followed by one cleaning stage at pH 11 with further addition of sodium cyanide, 3418A collector and MIBC frother to produce an upgraded lead concentrate. The rougher tails from the copper/lead separation float constitute the copper concentrate.
- The copper/lead rougher tails and the copper/lead first cleaner tails, feed to the zinc rougher float, are conditioned at pH 11.8 adjusted with lime in the presence of copper sulphate activator.
- Zinc rougher flotation using Aero 5100 as collector with further lime addition to maintain pH 11.8 and further MIBC frother addition.
- Regrind of the zinc rougher concentrate to a target $\mathrm{P}_{80}$ of 15 to $20 \mu \mathrm{~m}$ in the presence of additional copper sulphate activator and additional lime to maintain pH 12.
- The reground zinc rougher concentrate was submitted to four zinc cleaning stages with further additions of lime to maintain pH 12 , and further Aero 5100 collector addition. The use of sodium metabisulphite (NaMBS) in the zinc cleaners improved the zinc grade to the final zinc cleaner concentrate.

## Results of Lock Cycle Tests

A total of eight lock cycle tests were completed to quantify recoveries and concentrate grades for the Keg Main Zone mineralization under conditions approaching steady state. Results are summarized in the table below.

| Silver Range Resources Ltd. - Keg Main Zone Metallurgical Testwork Summary of Lock Cycle Test Results |  |  |  |  |  |  |  |  |  |

| Overall NaMBS | 1.36 | 0.31 | 0.27 | 41.6 | 11.4 | 87.7 | 86.0 | 69.2 | 83.4 | 85.5 |

Notes: 1. Combined silver recovery to lead and copper concentrate
2. Combined indium recovery to zinc and copper concentrate

The results of the lock cycle tests on all test composites show that the Keg Main Zone mineralization responds very well to typical copper/lead/zinc flotation circuits with excellent recoveries of payable metals and acceptable copper, lead and zinc concentrate grades in copper, lead and zinc concentrates. General comments and observations on the lock cycle results include the following:

- There was generally good agreement between the results of the Overall Composite and the average results of the six variability composites, both with respect to grades and recoveries.
- Zinc concentrate grades of greater than $45 \% \mathrm{Zn}$ were achievable on composites with head grades greater than $1.0 \% \mathrm{Zn}$. The use of sodium metabisulphite (NaMBS) in the zinc cleaner circuit leads to a higher zinc grade in the zinc concentrate (approaching $50 \% \mathrm{Zn}$ ) without impacting on zinc recovery.
- The lead grade in the lead concentrate, which averaged $65 \% \mathrm{~Pb}$, was independent of the head grade of the composites. Excellent lead concentrate grades were achieved even down to a low head grade of $0.15 \% \mathrm{~Pb}$. The lower lead concentrate grade in the lead concentrate from the last lock cycle test ( $59.4 \% \mathrm{~Pb}$ versus $65.5 \% \mathrm{~Pb}$ in the first lock cycle test) was due to an increase in cleaner flotation time in the copper/lead cleaner float, which pulled more weight to the third copper/lead cleaner concentrate and impacted on copper/lead separation.
- Excellent copper grades were obtained in the copper concentrate, averaging $27.2 \% \mathrm{Cu}$, even for the composites with relatively low copper head grade.
- Zinc recoveries to zinc concentrate averaged $88.6 \%$ and were generally over $90 \%$ for composites with zinc head grades greater than $1.0 \% \mathrm{Zn}$.
- Lead recoveries to lead concentrate averaged $82.4 \%$ and were all greater than $80 \%$ except for the one composite with a low lead head grade which had a $77.5 \%$ lead recovery for a $0.15 \% \mathrm{~Pb}$ head grade, still quite acceptable for a low head grade.
- Copper recoveries averaged $69.4 \%$ and generally followed copper head grade, ranging from $80.2 \%$ recovery for a $0.60 \% \mathrm{Cu}$ head grade to $59.0 \%$ for a $0.10 \% \mathrm{Cu}$ head grade.
- Excellent silver recoveries were achieved, averaging 57.2\% recovery to lead concentrate assaying an average of $5,816 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$, and $22.7 \%$ recovery to copper concentrate assaying an average of $1,458 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$. A minor amount, an average of $8.2 \%$, reported to the zinc concentrate which assayed an average of $136 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$. Silver head grade did not have much impact on overall silver recovery.
- The majority of the recoverable indium reported to the zinc concentrate, averaging $74.3 \%$ recovery and assaying an average of 320 g In/t. A lesser amount, $8.6 \%$, was recovered to the copper concentrate assaying an average of $150 \mathrm{~g} \mathrm{In} / \mathrm{t}$. No indium reported to the lead concentrate. Indium head grade did not seem to have an impact on overall indium recovery.
- The average tin grades were $1.99 \% \mathrm{Sn}$ in the copper concentrate, $0.44 \% \mathrm{Sn}$ in the lead concentrate and $0.04 \%$ in the zinc concentrate. The majority of the tin, an average of $60 \%$, was not recovered and reported to the final float tails which had an average tails tin assay of $0.025 \% \mathrm{Sn}$.

## Concentrate Analyses

Key analyses of the copper, lead and zinc concentrates, composites of the concentrates from the six cycles (A-F) of the lock cycle tests, are summarized in the table below. These analyses can be used as preliminary data in marketing studies and for developing smelter terms for each concentrate.

| Element | Unit | Overall Comp. | Comp A | Comp B | Comp C | Comp D | Comp E | Comp F |

A static settling test was completed on the zinc flotation tailings from Test LCT1. This test showed that a thickened tailings density of $69 \%$ solids ( $\mathrm{w} / \mathrm{w}$ ) could be achieved using a feed pulp density of $10 \%$ solids (w/w) and a Magnafloc 10 flocculant dosage of $8 \mathrm{~g} / \mathrm{t}$. Allowing for a $25 \%$ design factor the thickener unit area was measured at $0.10 \mathrm{~m}^{2} / \mathrm{t} /$ day implying that the Silver Range flotation tailings settle relatively well.

### 13.2 INTRODUCTION

Metallurgical testwork on the Keg Main Zone of the Silver Range Project was completed at SGS Canada Inc. - Lakefield Research located in Lakefield Ontario in 2012.

The testwork, completed on six variability composites and one overall composite, encompassed preparation and analyses of test composites, comminution testing, open cycle and lock cycle flotation tests, gravity recovery tests, concentrate analyses and tailings physical and chemical characterization.
The results of the test program were used to arrive at a suitable process flowsheet and to provide metallurgical efficiencies for project evaluation, as well as providing concentrate analyses for market evaluation and preliminary tailings characteristics for use in environmental studies.

### 13.3 COMPOSITE PREPARATION AND ANALYSES

A set of diamond drill hole (DDH) coarse assay reject samples, collected from 11 drill holes over a strike length of 600 m , were collected and sent to SGS Canada Inc.'s Vancouver laboratory to prepare test composites for metallurgical testwork. Sample collection and composite preparation instructions were prepared by Archer, Cathro \& Associates (1981) Limited.

A total of six variability composites of approximately 100 kg each were prepared to represent distinct zones of the known mineralization, designated as Composites A, B, C, D, E, and F. The drill core calculated grades for these six composites are summarized in Table 13.1 below.

| Table 13.1 <br> Silver Range Resources Ltd. - Keg Main Zone Metallurgical Testwork Test Composites - Drill Core Calculated Grades for Key Elements |  |  |  |  |  |  |  |  |

For the initial testwork a portion of each variability composite was taken and mixed, on a weighted basis, to prepare an overall master composite.

Samples of each prepared composite were submitted for detailed head analyses. Key elemental analyses are summarized in Table 13.2 and detailed analyses are listed in Table 13.3.

A comparison of the expected drill core calculated head grades in Table 13.1 against the assay head grades of the test composites listed in Table 13.2 shows good agreement for copper, lead and zinc, good agreement for indium, reasonable agreement for tin and, except for Composite A, good agreement for silver.

The metallics silver assay on Composite A carried out at 150 mesh ( $81.7 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$ versus the assay head grade of $89.1 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$ and the drill core calculated grade of $73.7 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$ ) suggests the presence of "coarse silver" but only $0.1 \%$ of the silver was in the plus 150 mesh fraction.

Mineralogical examination of the Overall Composite, a blend of the six variability composites, was completed to quantify the mode of occurrence of minerals of interest. Quartz is the dominant mineral in all size fractions accounting for 30.6 \% of the Overall Composite sample, followed by pyroxene, K-feldspar and plagioclase which account for $22.1 \%, 12.2 \%$ and $8.1 \%$ of the sample
respectively. Calcite accounts for 5.7 \%, epidote for $5.2 \%$, chlorite for $3.0 \%$ and titanite for 2.0 \%.

The sulphides consist mainly of sphalerite ( 2.6 \%), pyrite ( $2.2 \%$ ), chalcopyrite (1.1 \%), pyrrhotite ( $0.7 \%$ ), arsenopyrite ( $0.4 \%$ ) and galena ( $0.5 \%$ ). Other minerals are present in trace amounts ( $<1 \%$ ). Traces of silver minerals (native silver and silver sulphides) were found, but more detailed examination specific to silver would be required to properly define the mode of occurrence of silver. The main tin minerals, which are typically fine grained, include stannite ( $0.2 \%$ ) and rare cassiterite ( $0.01 \%$ ).
The overall composite was submitted to a gravity recoverable test under the standard conditions used for a GRG (Gravity Recoverable Gold) test. The test gravity recovery value for silver was $25 \%$ which implies that approximately $15 \%$ of the silver could be recoverable by gravity under plant operating conditions. The test gravity recovery value for tin was $5.1 \%$ which implies that only about $3 \%$ of the tin could be recovered by gravity under plant operating conditions.

### 13.4 COMMINUTION DATA

Each composite was submitted to a Bond Ball Mill Work Index test to provide some initial information on the grinding characteristics of the Keg Main Zone mineralization. Results are summarized in Table 13.4 below. Except for Composite D which was slightly harder, all composites suggest that the Keg Main Zone mineralization is of medium hardness.

### 13.5 FLOTATION TESTWORK

### 13.5.1 Batch Flotation Tests

A total of 16 open cycle batch flotation tests were completed on the overall composite to identify the flotation characteristics of the Keg main zone mineralization and to quantify optimum flotation parameters for the recovery of copper, lead and zinc to concentrates. Six open cycle batch flotation tests were also completed on the six variability composites, one per composite to assess variability ahead of lock cycle testing.
Initial rougher flotation tests indicated that target rougher recoveries to a bulk copper/lead rougher concentrate would be approaching $90 \%$ for copper, lead and silver with a mass pull of about $3 \%$. The target zinc rougher recovery to a bulk zinc rougher concentrate was in the range of $80 \%$ to $90 \%$ with a mass pull of about $7 \%$.
Coarsening the primary grind from a $\mathrm{P}_{80}$ of $59 \mu \mathrm{~m}$ to a $\mathrm{P}_{80}$ of $195 \mu \mathrm{~m}$ caused a $4 \%$ drop in copper rougher recovery, a $6 \%$ drop in zinc rougher recovery and a $3 \%$ drop in silver rougher recovery. Lead liberation was good in all tests, even at the coarser grind $\mathrm{P}_{80}$ of $195 \mu \mathrm{~m}$ which yielded an acceptable lead rougher recovery of $92 \%$. A $\mathrm{P}_{80}$ of $100 \mu \mathrm{~m}$ was chosen as the target primary grind.
Increasing the fineness of the copper/lead rougher concentrate regrind increased copper recovery to the copper/lead third cleaner concentrate and to the final copper concentrate with no impact on copper grade in the concentrate. Adding a single lead cleaning stage to the lead was required to maximize lead concentrate grade. Adding cyanide to control redox potential in the copper/lead separation float likely enhanced copper/lead separation.

A slightly finer regrind of the zinc cleaner feed and adding a fourth cleaning stage improved the zinc grade in the final zinc cleaner to above $40 \% \mathrm{Zn}$. Increasing the collector dosage in the zinc cleaning stage did not increase zinc recovery.

Batch testing showed that complete replacement of sodium cyanide with NaMBS (sodium metabisulphite) resulted in poor copper/lead separation and a drop in zinc recovery to the fourth cleaner concentrate with only a slight improvement in zinc concentrate grade. The use of NaMBS in the zinc cleaner circuit improved the zinc concentrate grade to $48.5 \% \mathrm{Zn}$ with four cleaners, compared to the $46.9 \% \mathrm{Zn}$ grade
achieved with five cleaners or the $43.4 \% \mathrm{Zn}$ grade achieved with four cleaners in a previous test.

The majority of the silver, about $80 \%$ to $85 \%$, reports to the copper/lead rougher concentrate and possibly $5 \%$ to $10 \%$ is expected to report to the zinc concentrate. In the downstream copper/lead separation float, as expected, the silver mostly reports to the lead concentrate.

Preliminary values for indium recovery suggested that about $40 \%$ to $75 \%$ of the indium could report to a zinc concentrate assaying above $45 \% \mathrm{Zn}$ and about 400 g $\mathrm{In} / \mathrm{t}$. A small amount of the indium, less than $10 \%$, would report to the copper concentrate.

About half the tin reports to the copper/lead rougher concentrate. Separate tin recovery by flotation proved difficult and was therefore not pursued further in this test program.

In open cycle batch tests on the six variability composites there was no direct correlation between head grade and recovery and grade in concentrate for zinc and lead which implies that there are other (mineralogical) factors affecting recovery and deportment of zinc and lead to concentrate. Copper on the other hand generally showed increasing recovery and copper grade to copper concentrate with increasing head grade.

### 13.5.2 Selection of Flotation Conditions and Reagent Scheme

Based on the results of the open cycle batch flotation tests, the flowsheet selected for separate recovery of copper, lead, and zinc concentrates in lock cycle tests is depicted in Figures 13.1 and 13.2 below.

Figure 13.1
Silver Range Project -Lock Cycle Test Flowsheet Copper/Lead Circuit
(from SGS Canada Inc. Lakefield Research)

Figure 13.2
Silver Range Project - Lock Cycle Test Flowsheet Zinc Circuit
(from SGS Canada Inc. Lakefield Research)

The flotation conditions and reagent scheme generally used in the lock cycle tests were as follows:

- Target primary grind $\mathrm{P}_{80}$ of $100 \mu \mathrm{~m}$ in the presence of $200 \mathrm{~g} / \mathrm{t}$ lime $(\mathrm{pH} 8$ to 8.5).
- A five minute pulp aeration time ahead of copper/lead rougher flotation.
- Copper/lead rougher flotation using Aerophine 3418A (10 g/t) as collector and MIBC (methyl isobutyl carbinol) ( $22.5 \mathrm{~g} / \mathrm{t}$ ) as frother with a six minute laboratory flotation time at pH 9 to 9.5 controlled with further addition of lime (approximately $250 \mathrm{~g} / \mathrm{t}$ ).
- Regrind of the copper/lead rougher concentrate to a target $\mathrm{P}_{80}$ of 20 to $25 \mu \mathrm{~m}$ in the presence of zinc sulphate ( $75 \mathrm{~g} / \mathrm{t}$ ) and sodium cyanide ( $12.5 \mathrm{~g} / \mathrm{t}$ ) used as zinc depressant, additional lime ( $75 \mathrm{~g} / \mathrm{t}$ ) to maintain an elevated $\mathrm{pH}(\mathrm{pH} 9)$ and additional 3418A collector ( $5 \mathrm{~g} / \mathrm{t}$ ).
- Three stages of copper/lead cleaners, approximately 4 minutes per stage, with further 3418A collector addition ( $5 \mathrm{~g} / \mathrm{t}$ ) and lime addition (approximately $50 \mathrm{~g} / \mathrm{t}$ ) to maintain pH 10 , and $15 \mathrm{~g} / \mathrm{t}$ MIBC frother addition.
- Copper/lead separation one minute rougher float on the third copper/lead cleaner concentrate at pH 11 in the presence of sodium cyanide (approximately $400 \mathrm{~g} / \mathrm{t}$ ), additional 3418A collector ( $2.5 \mathrm{~g} / \mathrm{t}$ ) and MIBC frother ( $2.5 \mathrm{~g} / \mathrm{t}$ ); followed by one two minute cleaning stage at pH 11 with further addition of sodium cyanide (approximately $160 \mathrm{~g} / \mathrm{t}$ ), 3418A collector ( $2.5 \mathrm{~g} / \mathrm{t}$ ) and MIBC frother ( $2.5 \mathrm{~g} / \mathrm{t}$ ) to produce an upgraded lead concentrate. The copper/lead separation rougher tails constitute the copper concentrate.
- The copper/lead rougher tails and the copper/lead first cleaner tails are fed to the zinc flotation circuit consisting of rougher and cleaner floats.
- The feed to the zinc rougher float is conditioned at pH 11.8 adjusted with lime (approximately $1300 \mathrm{~g} / \mathrm{t}$ ) and with copper sulphate activator ( $250 \mathrm{~g} / \mathrm{t}$ ).
- Zinc rougher flotation consists of a six to eight minute flotation time using Aero 5100 as collector ( $25 \mathrm{~g} / \mathrm{t}$ ) with further lime addition (approximately $350 \mathrm{~g} / \mathrm{t}$ ) to maintain pH 11.8 and further MIBC frother addition ( $20 \mathrm{~g} / \mathrm{t}$ ).
- Regrind of the zinc rougher concentrate to a target $\mathrm{P}_{80}$ of 15 to $20 \mu \mathrm{~m}$ in the presence of additional copper sulphate activator (approximately $50 \mathrm{~g} / \mathrm{t}$ ) and additional lime (approximately 500 to $750 \mathrm{~g} / \mathrm{t}$ ) to maintain an elevated pH ( pH 12 ).
- The reground zinc rougher concentrate was submitted to four zinc cleaning stages with further additions of lime (varying from 200 to $800 \mathrm{~g} / \mathrm{t}$ ) to maintain pH 12 , and further Aero 5100 collector addition ( $7.5 \mathrm{~g} / \mathrm{t}$ ). One additional lock cycle test evaluated the use of sodium metabisulphite (NaMBS) in the zinc cleaners (total addition of $375 \mathrm{~g} / \mathrm{t}$ ), which improved the zinc grade to the final zinc cleaner concentrate.

### 13.5.3 Lock Cycle Flotation Tests

A total of eight lock cycle tests were completed to quantify recoveries and concentrate grades for the Keg Main Zone mineralization under conditions approaching steady state. One lock cycle test was completed on each variability composite and two lock cycle tests were completed on the overall composite to test the effect of sodium metabisulphite (NaMBS) in the zinc cleaner float. It is noted that increasing the cleaner float time in the copper/lead cleaner float in this test resulted in a slightly negative impact on copper/lead separation.
As summarized in Tables 13.5 and 13.6 below, the results of the lock cycle tests on all test composites show that the Keg Main Zone mineralization responds very well to typical copper/lead/zinc flotation circuits with excellent recoveries of payable metals and acceptable copper, lead and zinc concentrate grades in copper, lead and zinc concentrates.

Notes: 1. Combined silver recovery to lead and copper concentrate
2. Combined indium recovery to zinc and copper concentrate
3. The average values are an average of the Composites A to F results.
4. The overall values are the results of the test on the Overall Composite, a blend of Composites A to
F.
5. The overall NaMBS values are the results of the test on the Overall Composite using NaMBS in the zinc cleaner float.

General comments and observations on the lock cycle results include the following:

- There was generally good agreement between the results of the Overall Composite and the average results of the six variability composites, both with respect to grades and recoveries.
- Zinc concentrate grades of greater than $45 \% \mathrm{Zn}$ were achievable on composites with head grades greater than $1.0 \% \mathrm{Zn}$. The use of sodium metabisulphite (NaMBS) in the zinc cleaner circuit leads to a higher zinc grade in the zinc concentrate (approaching $50 \% \mathrm{Zn}$ ) without impacting on zinc recovery.
- The lead grade in the lead concentrate, which averaged $65 \% \mathrm{~Pb}$, was independent of the head grade of the composites. Excellent lead concentrate grades were achieved even down to a low head grade of $0.15 \% \mathrm{~Pb}$ in Composite E. The lower lead concentrate grade in the lead concentrate from the last lock cycle test ( $59.4 \% \mathrm{~Pb}$ versus $65.5 \% \mathrm{~Pb}$ in the first lock cycle test) was due an increase in cleaner flotation time in the copper/lead cleaner
float, which pulled more weight to the third copper/lead cleaner concentrate and impacted on copper/lead separation.
- Excellent copper grades were obtained in the copper concentrate, averaging $27.2 \% \mathrm{Cu}$, even for the composites with relatively low copper head grade. For example Composite D with a copper head grade of only $0.10 \% \mathrm{Cu}$ achieved a $25.2 \% \mathrm{Cu}$ concentrate grade.
- Zinc recoveries to zinc concentrate averaged $88.6 \%$ and were generally over $90 \%$ for composites with zinc head grades greater than $1.0 \% \mathrm{Zn}$.
- Lead recoveries to lead concentrate averaged $82.4 \%$ and were all greater than $80 \%$ except for the one composite with a low lead head grade which had a $77.5 \%$ lead recovery for a $0.15 \% \mathrm{~Pb}$ head grade, still quite acceptable for a low head grade.
- Copper recoveries averaged $69.4 \%$ and generally followed copper head grade, ranging from $80.2 \%$ recovery for a $0.60 \% \mathrm{Cu}$ head grade (Composite B) to $59.0 \%$ for a $0.10 \% \mathrm{Cu}$ head grade (Composite D).
- Excellent silver recoveries were achieved, averaging 57.2\% recovery to lead concentrate assaying an average of $5,816 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$, and $22.7 \%$ recovery to copper concentrate assaying an average of $1,458 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$. A minor amount, an average of $8.2 \%$, reported to the zinc concentrate which assayed an average of $136 \mathrm{~g} \mathrm{Ag} / \mathrm{t}$. Silver head grade did not have much impact on overall silver recovery.
- The majority of the recoverable indium reported to the zinc concentrate, averaging $74.3 \%$ recovery and assaying an average of 320 g In/t. A lesser amount, $8.6 \%$, was recovered to the copper concentrate assaying an average of $150 \mathrm{~g} \mathrm{In} / \mathrm{t}$. No indium reported to the lead concentrate. Indium head grade did not seem to have an impact on overall indium recovery.
- The average tin grades were $1.99 \% \mathrm{Sn}$ in the copper concentrate, $0.44 \% \mathrm{Sn}$ in the lead concentrate and $0.04 \%$ in the zinc concentrate. The majority of the tin, an average of $60 \%$, was not recovered and reported to the final float tails which had an average tails tin assay of $0.025 \% \mathrm{Sn}$.

### 13.6 CONCENTRATE ANALYSES

Available detailed analyses of the copper, lead and zinc concentrates, composites of the concentrates from the six cycles (A-F), are summarized in Tables 13.7, 13.8 and 13.9 below for the first lock cycle test completed on the Overall Composite, Test LCT1, and for the lock cycle tests completed on the six variability composites, Tests LCT 2 to LCT7. These analyses can be used as preliminary data in marketing studies and for developing smelter terms for each concentrate.

### 13.7 TAILINGS PHYSICAL AND CHEMICAL CHARACTERIZATION

### 13.7.1 Tailings Analyses

The combined zinc flotation tailings solids and tailings supernatant from the first lock cycle test were submitted to a detailed analysis. The tailings were also submitted to tailings aging tests with analysis of the supernatant at regular intervals. The tailings solids analyses are summarized in Table 13.10 and the tailings aging test results to Day 28 are summarized in Table 13.11. These data can be used in preliminary environmental studies for the project.

### 13.7.2 Tailings Settling Test

A static settling test was completed on the zinc flotation tailings from Test LCT1. This test showed that a thickened tailings density of $69 \%$ solids (w/w) could be achieved using a feed pulp density of $10 \%$ solids (w/w) and a Magnafloc 10 flocculant dosage of $8 \mathrm{~g} / \mathrm{t}$. The thickener unit area was measured at $0.08 \mathrm{~m}^{2} / \mathrm{t} / \mathrm{day}$. Allowing for a $25 \%$ design factor the net thickener area would be $0.10 \mathrm{~m}^{2} / \mathrm{t} /$ day, which implies that the Silver Range flotation tailings settle relatively well.
